**MODULATORS OF BODY WEIGHT, CORRESPONDING NUCLEIC
ACIDS AND PROTEINS, AND DIAGNOSTIC AND THERAPEUTIC USES
THEREOF**

Ins a'

- The research leading to the present inventions was funded in part by Grant No.
- 5 DK 41096 from the National Institutes of Health. The government may have certain rights in the invention.

RELATED APPLICATIONS

- The present application is a continuation-in-part of copending application Serial No. 08/347,563, filed November 30, 1994, which in turn is a continuation-in-part
- 10 of copending application Serial No. 08/292,345, filed August 17, 1994, of which the instant application claims the benefit of the filing date pursuant to 35 U.S.C. § 120, and each of which is incorporated herein by reference in its entirety.

TECHNICAL FIELD OF THE INVENTION

- The present invention relates generally to the control of body weight of mammals
- 15 including animals and humans, and more particularly to materials identified herein as modulators of weight, and to the diagnostic and therapeutic uses to which such modulators may be put.

BACKGROUND OF THE INVENTION

- Obesity, defined as an excess of body fat relative to lean body mass, is associated
- 20 with important psychological and medical morbidities, the latter including hypertension, elevated blood lipids, and Type II or non-insulin-dependent diabetes melitis (NIDDM). There are 6-10 million individuals with NIDDM in the U.S., including 18% of the population of 65 years of age (Harris *et al.*, 1987). Approximately 45% of males and 70% of females with NIDDM are obese, and
- 25 their diabetes is substantially improved or eliminated by weight reduction (Harris, 1991). As described below, both obesity and NIDDM are strongly heritable,

000780"4985E960

though the predisposing genes have not been identified. The molecular genetic basis of these metabolically related disorders is an important, poorly understood problem.

5 The assimilation, storage, and utilization of nutrient energy constitute a complex homeostatic system central to survival of metazoa. Among land-dwelling mammals, storage in adipose tissue of large quantities of metabolic fuel as triglycerides is crucial for surviving periods of food deprivation. The need to maintain a fixed level of energy stores without continual alterations in the size and shape of the organism requires the achievement of a balance between energy intake and expenditure. However, the molecular mechanisms that regulate energy balance remain to be elucidated. The isolation of molecules that transduce nutritional information and control energy balance will be critical to an understanding of the regulation of body weight in health and disease.

15 An individual's level of adiposity is, to a large extent, genetically determined. Examination of the concordance rates of body weight and adiposity amongst mono- and dizygous twins or adoptees and their biological parents have suggested that the heritability of obesity (0.4-0.8) exceeds that of many other traits commonly thought to have a substantial genetic component, such as schizophrenia, alcoholism, and atherosclerosis (Stunkard *et al.*, 1990). Familial similarities in rates of energy expenditure have also been reported (Bogardus *et al.*, 1986). Genetic analysis in geographically delimited populations has suggested that a relatively small number of genes may account for the 30%-50% of variance in body composition (Moll *et al.*, 1991). However, none of the genes responsible for obesity in the general population have been genetically mapped to a definite chromosomal location.

Rodent models of obesity include seven apparently single-gene mutations. The most intensively studied mouse obesity mutations are the *ob* (obese) and *db*

(diabetes) genes. When present on the same genetic strain background, *ob* and *db* result in indistinguishable metabolic and behavioral phenotypes, suggesting that these genes may function in the same physiologic pathway (Coleman, 1978). Mice homozygous for either mutation are hyperphagic and hypometabolic, leading to an obese phenotype that is notable at one month of age. The weight of these animals tends to stabilize at 60-70 g (compared with 30-35 g in control mice). *ob* and *db* animals manifest a myriad of other hormonal and metabolic changes that have made it difficult to identify the primary defect attributable to the mutation (Bray *et al.*, 1989).

- 10 Each of the rodent obesity models is accompanied by alterations in carbohydrate metabolism resembling those in Type II diabetes in man. In some cases, the severity of the diabetes depends in part on the background mouse strain (Leiter, 1989). For both *ob* and *db*, congenic C57BL/Ks mice develop a severe diabetes with ultimate β cell necrosis and islet atrophy, resulting in a relative insulinopenia.
- 15 Conversely, congenic C57BL/6J *ob* and *db* mice develop a transient insulin-resistant diabetes that is eventually compensated by β cell hypertrophy resembling human Type II diabetes.

The phenotype of *ob* and *db* mice resembles human obesity in ways other than the development of diabetes - the mutant mice eat more and expend less energy than do lean controls (as do obese humans). This phenotype is also quite similar to that seen in animals with lesions of the ventromedial hypothalamus, which suggests that both mutations may interfere with the ability to properly integrate or respond to nutritional information within the central nervous system. Support for this hypothesis comes from the results of parabiosis experiments (Coleman, 1973) that suggest *ob* mice are deficient in a circulating satiety factor and that *db* mice are resistant to the effects of the *ob* factor (possibly due to an *ob* receptor defect). These experiments have led to the conclusion that obesity in these mutant mice may result from different defects in an afferent loop and/or integrative center of the postulated feedback mechanism that controls body composition.

- Using molecular and classical genetic markers, the *ob* and *db* genes have been mapped to proximal chromosome 6 and midchromosome 4, respectively (Bahary *et al.*, 1990; Friedman *et al.*, 1991b). In both cases, the mutations map to regions of the mouse genome that are syntenic with human, suggesting that, if there are human homologs of *ob* and *db*, they are likely to map, respectively, to human chromosomes 7q and 1p. Defects in the *db* gene may result in obesity in other mammalian species: in genetic crosses between Zucker *fa/fa* rats and Brown Norway *+/+* rats, the *fa* mutation (rat chromosome 5) is flanked by the same loci that flank *db* in mouse (Truett *et al.*, 1991).
- Because of the myriad factors that seem to impact body weight, it is difficult to speculate as to which of these factors, and more particularly, which homeostatic mechanism is actually primarily determinative. Nonetheless, the apparent connection between the *ob* gene and the extent and characteristics of obesity have prompted the further investigation and elucidation that is reflected by the present application. It is the identification of the sequence of the gene and corresponding peptide materials, to which the present invention following below directs itself.

The citation of any reference herein should not be construed as an admission that such reference is prior art to the instant invention. Full citations of references cited by author and year are found at the end of the specification.

20

SUMMARY OF THE INVENTION

- In its broadest aspect, the present invention relates to the elucidation and discovery of nucleotide sequences, and proteins putatively expressed by such nucleic acids or degenerate variations thereof, that demonstrate the ability to participate in the control of mammalian body weight. The nucleotide sequences in object are believed to represent the genes corresponding to the murine and human *ob* gene, that is postulated to play a critical role in the regulation of body weight and adiposity. Data presented herein indicates that the polypeptide product of the gene

In addition, the Examples herein demonstrate that the ob polypeptide, alternatively termed herein "leptin," circulates in mouse, rat, and human plasma. Leptin is absent in plasma from ob/ob mice, and is present at ten-fold higher concentrations in plasma from db/db mice, and twenty-fold higher concentrations in fa/fa rats. Most significantly, daily injections of recombinant leptin dramatically reduces the body mass of ob/ob mice, significantly effects the body weight of wild-type mice, and has no effect on db/db mice.

- In a first instance, the modulators of the present invention comprise nucleic acid molecules, including recombinant DNA molecules (*e.g.*, cDNA or a vector containing the cDNA or isolated genomic DNA) or cloned genes (*i.e.* isolated genomic DNA), or degenerate variants thereof, which encode polypeptides themselves serving as modulators of weight control as hereinafter defined, or conserved variants or fragments thereof, particularly such fragments lacking the signal peptide (alternatively referred to herein as mature ob polypeptide), which polypeptides possess amino acid sequences such as set forth in FIGURE 1 (SEQ ID NO:2), FIGURE 3 (SEQ ID NO:4), FIGURE 5 (SEQ ID NO:5) and FIGURE 6 (SEQ ID NO:6). In specific embodiments, amino acid sequences for two variants of murine and human ob polypeptides are provided. Both polypeptides are found in a form with glutamine 49 deleted, which may result from an mRNA splicing anomaly. The ob polypeptides from various species may be highly homologous; as shown in Figure 4, murine and human ob polypeptides are greater than 80% homologous.

The nucleic acid molecules, recombinant DNA molecules, or cloned genes, may have the nucleotide sequences or may be complementary to DNA coding sequences shown in FIGURE 1 (SEQ ID NO:1) and FIGURE 2 (SEQ ID NO:3). In particular, such DNA molecules can be cDNA or genomic DNA isolated from the chromosome. Nucleic acid molecules of the invention may also correspond to 5' and 3' flanking sequences of the DNA. Accordingly, the present invention also relates to the identification of a gene having a nucleotide sequence selected from the sequences of Figure 1 (SEQ ID NO:1) and Figure 2 (SEQ ID NO:3) herein, and degenerate variants, allelic variations, and like cognate molecules.

- 10 A nucleic acid molecule of the invention can be DNA or RNA, including synthetic variants thereof having phosphate or phosphate analog, *e.g.*, thiophosphate, bonds. Both single stranded and double stranded sequences are contemplated herein.

The present invention further provides nucleic acid molecules for use as molecular probes, or as primers for polymerase chain reaction (PCR) amplification, *i.e.*, synthetic or natural oligonucleotides having a sequence corresponding to a portion of the sequences shown in Figure 1 (SEQ ID NO:1), Figure 2 (SEQ ID NO:3) and Figure 20A (SEQ ID NO:22), or the 5' and 3' flanking sequences of the coding sequences. In particular, the invention contemplates a nucleic acid molecule having at least about 10 nucleotides, wherein a sequence of the nucleic acid molecule corresponds to a nucleotide sequence of the same number of nucleotides in the nucleotide sequences of Figure 1 (SEQ ID NO:1), Figure 2 (SEQ ID NO:3) and Figure 20A (SEQ ID NO:22), or a sequence complementary thereto. More preferably, the nucleic acid sequence of the molecule has at least 15 nucleotides. Most preferably, the nucleic acid sequence has at least 20 nucleotides. In an embodiment of the invention in which the oligonucleotide is a probe, the oligonucleotide is detectably labeled, *e.g.*, with a radionuclide (such as ³²P), or an enzyme.

In further aspects, the present invention provides a cloning vector, which comprises the nucleic acids of the invention that encode the ob polypeptide; and a bacterial, insect, or a mammalian expression vector, which comprises the nucleic acid molecules of the invention encoding the ob polypeptide, operatively associated with an expression control sequence. Accordingly, the invention further relates to a host cell, such as a bacterial cell, yeast cell, insect cell, or a mammalian cell, transfected or transformed with an appropriate expression vector, and correspondingly, to the use of the above mentioned constructs in the preparation of the modulators of the invention.

- 10 In yet a further aspect, the present invention relates to antibodies that bind to the ob polypeptide. Such antibodies may be generated against the full length polypeptide, or antigenic fragments thereof. In one aspect, such antibodies inhibit the functional (*i.e.*, body weight and fat composition modulating) activity of the ob polypeptide. In another aspect, antibodies can be used to determine the level of circulating ob polypeptide in plasma or serum. In yet a further aspect, regio-specific antibodies, particularly monoclonal antibodies, can be used as probes of ob polypeptide structure.

All of the foregoing materials are to be considered herein as modulators of body weight and fat composition, and as such, may be used in a variety of contexts.

- 20 Specifically, the invention contemplates both diagnostic and therapeutic applications, as well as certain agricultural applications, all contingent upon the use of the modulators defined herein, including both nucleic acid molecules and peptides. Moreover, the modulation of body weight carries specific therapeutic implications and benefits, in that conditions where either obesity or, conversely, cachexia represent undesired bodily conditions, can be remedied by the administration of one or more of the modulators of the present invention.

Thus, a method for modulating body weight of a mammal is proposed that comprises controlling the expression of the protein encoded by a nucleic acid

09635864.081000

having nucleotide sequence selected from the sequence of Figure 1 (SEQ ID NO:1), the sequence of Figure 2 (SEQ ID NO:3) and degenerate and allelic variants thereof. Such control may be effected by the introduction of the nucleotides in question by gene therapy into fat cells of the patient or host to control or reduce obesity. Conversely, the preparation and administration of antagonists to the nucleotides, such as anti-sense molecules, would be indicated and pursued in the instance where conditions involving excessive weight loss, such as anorexia nervosa, cancer, or AIDS are present and under treatment. Such constructs would be introduced in similar fashion to the nucleotides, directly into fat cells to effect such changes.

Correspondingly, the proteins defined by Figures 1, 3, 5, and 6 (SEQ ID NO:1, SEQ ID NO:4, SEQ ID NO:5, and SEQ ID NO:6), conserved variants, active fragments thereof, and cognate small molecules could be formulated for direct administration for therapeutic purposes, to effect reduction or control of excessive body fat or weight gain. Correspondingly, antibodies and other antagonists to the stated protein materials, such as fragments thereof, could be prepared and similarly administered to achieve the converse effect. Accordingly, the invention is advantageously directed to a pharmaceutical composition comprising an ob polypeptide of the invention, or alternatively an antagonist thereof, in an admixture with a pharmaceutically acceptable carrier or excipient.

The diagnostic uses of the present nucleotides and corresponding peptides extend to the use of the nucleotides to identify further mutations of allelic variations thereof, so as to develop a repertoire of active nucleotide materials useful in both diagnostic and therapeutic applications. In particular, both homozygous and heterozygous mutations of the nucleotides in question could be prepared that would be postulated to more precisely quantitate the condition of patients, to determine the at-risk potential of individuals with regard to obesity. Specifically, heterozygous mutations are presently viewed as associated with mild to moderate obesity, while homozygous mutations would be associated with a more pronounced

and severe obese condition. Corresponding DNA testing could then be conducted utilizing the aforementioned ascertained materials as benchmarks, to facilitate an accurate long term prognosis for particular tendencies, so as to be able to prescribe changes in either dietary or other personal habits, or direct therapeutic
 5 intervention, to avert such conditions.

The diagnostic utility of the present invention extends to methods for measuring the presence and extent of the modulators of the invention in cellular samples or biological extracts (or samples) taken from test subjects, so that both the encoded nucleotide (genomic DNA or RNA) and or the levels of protein in such test
 10 samples could be ascertained. Given that the increased activity of the nucleotide and presence of the resulting protein reflect the capability of the subject to inhibit obesity, the physician reviewing such results in an obese subject would determine that a factor other than dysfunction with respect to the presence and activity of the nucleotides of the present invention is a cause of the obese condition. Conversely,
 15 depressed levels of the nucleotide and or the expressed protein would suggest that such levels must be increased to treat such obese condition, and an appropriate therapeutic regimen could then be implemented.

Further, the nucleotides discovered and presented in Figures 1 and 2 represent cDNA in which, as stated briefly above, is useful in the measurement of
 20 corresponding RNA. Likewise, recombinant protein material corresponding to the polypeptides of Figures 1 and 3 may be prepared and appropriately labeled, for use, for example, in radioimmunoassays, for example, for the purpose of measuring fat and/or plasma levels of the ob protein, or for detecting the presence and level of a receptor for ob on tissues, such as the hypothalamus.

25 Yet further, the present invention contemplates not only the identification of the nucleotides and corresponding proteins presented herein, but the elucidation of the receptor to such materials. In such context, the polypeptides of Figures 1, 3, 5, and/or 6 could be prepared and utilized to screen an appropriate expression library

09635864.081000

to isolate active receptors. The receptor could thereafter be cloned, and the receptor alone or in conjunction with the ligand could thereafter be utilized to screen for small molecules that may possess like activity to the modulators herein.

- Yet further, the present invention relates to pharmaceutical compositions that
- 5 include certain of the modulators hereof, preferably the polypeptides whose sequences are presented in SEQ ID NO:2, SEQ ID NO:4, SEQ ID NO:5 and SEQ ID NO:6, their antibodies, corresponding small molecule agonists or antagonists thereof, or active fragments prepared in formulations for a variety of modes of administration, where such therapy is appropriate. Such formulations would
- 10 include pharmaceutically acceptable carriers, or other adjuvants as needed, and would be prepared in effective dosage ranges to be determined by the clinician or the physician in each instance.

- Accordingly, it is a principal object of the present invention to provide modulators of body weight as defined herein in purified form, that exhibit certain
- 15 characteristics and activities associated with control and variation of adiposity and fat content of mammals.

- It is a further object of the present invention to provide methods for the detection and measurement of the modulators of weight control as set forth herein, as a means of the effective diagnosis and monitoring of pathological conditions wherein
- 20 the variation in level of such modulators is or may be a characterizing feature.

- It is a still further object of the present invention to provide a method and associated assay system for the screening of substances, such as drugs, agents and the like, that are potentially effective to either mimic or inhibit the activity of the modulators of the invention in mammals.
- 25 It is a still further object of the present invention to provide a method for the treatment of mammals to control body weight and fat content in mammals, and or

10

BRIEF DESCRIPTION OF THE DRAWINGS

15

FIGURE 2 depicts the nucleic acid sequence (SEQ ID NO:3) derived for the human *ob* cDNA. The nucleotides are numbered from 1 to 701 with a start site at nucleotide 46 and a termination at nucleotide 550.

FIGURE 3 depicts the full deduced amino acid sequence (SEQ ID NO:4) derived for the human *ob* gene corresponding to the nucleic acid sequence of FIGURE 2. The amino acids are numbered from 1 to 167. A signal sequence cleavage site is located after amino acid 21 (Ala) so that the mature protein extends from amino acid 22 (Val) to amino acid 167 (Cys).

FIGURE 4 depicts the comparison between the murine (SEQ ID NO:2) and human (SEQ ID NO:4) deduced amino acid sequences. The sequence of the human *ob* deduced amino acid sequence was highly homologous to that of mouse. Conservative changes are noted by a dash, and non-conservative changes by an asterisk. The variable glutamine codon is underlined, as is the position of the nonsense mutation in C57BL/6J *ob/ob* (1J) mice. Overall, there is 84% identity at the amino acid level, although only six substitutions were found between the valine at codon 22 (immediately downstream of the signal sequence overage) and the cysteine at position 117.

FIGURE 5 depicts the full length amino acid sequence (SEQ ID NO:5) derived for the murine *ob* gene as shown in FIGURE 3, but lacking glutamine at position 49. The nucleotides are numbered from 1 to 166. A signal sequence cleavage site is located after amino acid 21 (Ala) (and thus, before the glutamine 49 deletion) so that the mature protein extends from amino acid 22 (Val) to amino acid 166 (Cys).

FIGURE 6 depicts the full deduced amino acid sequence (SEQ ID NO:6) derived for the human *ob* gene as shown in FIGURE 4, but lacking glutamine at position 49. The nucleotides are numbered from 1 to 166. A signal sequence cleavage site is located after amino acid 21 (Ala) (and thus, before the glutamine 49 deletion) so that the mature protein extends from amino acid 22 (Val) to amino acid 166 (Cys).

FIGURE 7. (A) Physical map of the location of *ob* in the murine chromosome, and the YAC and P1 cloning maps. "M and N" corresponds to *MulI* and *NotI* restriction sites. The numbers correspond to individual animals that were

recombinant in the region of *ob* of the 1606 meioses that were scored. Met, Pax 4, D6Rck39, D6Rck13, and Cpa refer to locations in the region of *ob* that bind to the DNA probes. YACs were isolated using D6Rck13 and Pax-4 as probes, and the ends were recovered using vectorette PCR and/or plasmid end rescue and used

5 in turn to isolate new YACs. (B) The resulting YAC contig. One of the YACs in this contig, Y902A0925, was chimeric. Each of the probes used to genotype the recombinant animals is indicated in parentheses. (6) Corresponds to YAC 107; (5) corresponds to M16(+) (or M16(pLUS)); (4) corresponds to *adu*(+); (3) corresponds to *aad*(pICL); (2) corresponds to 53(pICL); and (1) corresponds to

10 53(+). (C) The P1 contig of bacteriophage P1 clones isolated with selected YAC end probes. The *ob* gene was isolated in a P1 clone isolated using the distal end of YAC YB6S2F12 (end (4)) (alternatively termed herein *adu*(+)).

FIGURE 8 presents a photograph of an ethidium bromide stain of 192 independent isolates of the fourth exon trapping experiment that were PCR amplified and

15 characterized.

FIGURE 9 is a photograph of an ethidium bromide stain of PCR-amplified clones suspected of carrying *ob*. Each of the 7 clones that did not carry the artifact was reamplified using PCR and electrophoresed on a 1% agarose gel in TBE and stained with ethidium bromide. The size markers (far left unnumbered lane) are

20 the commercially available "1 kB ladder". Lane 1 -- clone 1D12, containing an "HIV sequence." Lane 2 -- clone 1F1, a novel clone outside of the *ob* region. Lane 3 -- clone 1H3. Lane 4 -- clone 2B2, which is identical to 1F1. Lane 5 -- clone 2G7, which contains an *ob* exon. Lane 6 -- clone 2G11, which is identical to 1F1. Lane 7 -- clone 2H1, which does not contain an insert.

25 **FIGURE 10** presents the sequence of the 2G7 clone (SEQ ID NO:7), which includes an exon coding for a part of the *ob* gene. The primer sequences used to amplify this exon are boxed in the figure (SEQ ID NOS:8 and 9).

5

15

25

analysis was performed as in Figures 11 and 12. In this case, the control RNA was ap2, a fat specific transcript. There is no significance to the varying density of the ap2 bands.

FIGURE 14 compares the DNA sequence of the C57BL/6J (normal) and the C57BL/6J ob/ob (1J) mice in the region of the point mutation that leads to introduction of a premature stop codon (nonsense mutation) in the mutant strain cDNA. The ob/ob mice had a C→T mutation that changed an arginine residue at position 105. This base change is shown as the output from the automated DNA sequencer. RT-PCR was performed using white fat RNA from both strains (+/+ and ob/ob) using primers from the 5' and 3' untranslated regions. The PCR reaction products were gel purified and directly sequenced manually and using an ABI 373A automated sequencer with primers along both strands of the coding sequence.

FIGURE 15. (A) Genomic southern blot of genomic DNA from each of the mouse strains listed. Approximately 5 µg of DNA (derived from genomic DNA prepared from liver, kidney or spleen) was restriction digested with the restriction enzyme indicated. The DNA was then electrophoresed in a 1% agarose TBE gel and probed with PCR labeled 2G7. Restriction digestion with *Bgl*II revealed an increase in the size of an approximately 9 kB (the largest) *Bgl*II fragment in SM/Ckc-+Dacob^{2J}/ob^{2J} (2J) DNA. RFLPs were not detectable with any other restriction enzymes. Preliminary restriction mapping of genomic DNA indicated that the polymorphic *Bgl*II site is about 7 kB upstream of the transcription start site. None of the other enzymes tested extend past the mRNA start site. (B) Segregation of a *Bgl*II polymorphism in the SM/Ckc-+Dacob^{2J}/ob^{2J} strain. Six obese and five lean progeny from the same generation of the coisogenic SM/Ckc-+Dacob^{2J}/ob^{2J} (2J) colony were genotyped by scoring the *Bgl*II polymorphism as shown in (A). All of the phenotypically obese animals were homozygous for the larger allele of the polymorphic *Bgl* fragment. The DNA in

09635864.081000

the "control" lane was prepared from an unrelated SM/Ckc-+^{Dac}+/+ mouse, bred separately from the SM/Ckc-+^{Dac}ob^{2J}/ob^{2J} colony.

FIGURE 16 is a Southern blot of EcoRI digested genomic DNA from the species listed, using an *ob* cDNA as a probe (*i.e.*, a zoo blot). Hybridization signals were detectable in every vertebrate sample, even after a moderate stringency hybridization. The cat DNA in this experiment was slightly degraded. The restricted DNA was run on a 1% agarose TBE gel, and transferred to an imobilon membrane for probing. The filter was hybridized at 65°C and washed in 2X SSC/0.2% SDS at 65°C twice for twenty minutes and exposed for 3 days using Kodak X-OMAT film.

FIGURE 17 presents the expression cloning region of vector pET-15b (Novagen).

FIGURE 18 presents analysis of the eluate from a His-binding resin (Ni) column for a recombinant mature murine *ob* fusion to a His-tag (A) and mature human *ob* fusion to a His-tag (B). Bacteria transformed with vectors pETM9 and pETH14, respectively. Upon induction with 1 mM IPTG at optimal conditions, the transformed bacteria were able to produce 100-300 µg/ml of *ob* fusion protein, primarily in the inclusion body. The inclusion body was solubilized with 6M guanidine-HCl or urea, and fusion protein (present in the lysis supernatant) was loaded on the His-binding resin (Ni) column in 10 ml of 1x binding buffer with urea. The column was eluted stepwise with 5 ml aliquots of 20 µM, 60 µM, and 300 µM imidazole, and finally with strip buffer. The aliquots were analyzed for the presence of *ob* polypeptide fusion on a 15% acrylamide gel. Each lane contains the equivalent of 100 µl of bacterial extract.

FIGURE 19. (A) *In vitro* translation of *ob* RNA. A human *ob* cDNA was subcloned into the pGEM vector. The plasmid was linearized and plus strand RNA was synthesized using sp6 polymerase. The *in vitro* synthesized RNA was translated in the presence or absence of canine pancreatic microsomal membranes.

- An approximately 18 kD primary translation product was seen after *in vitro* translation. The addition of microsomal membranes to the reaction led to the appearance of a second translation product about 2 kD smaller than the primary translation product. The size of the translation product of interleukin-1 α RNA, which lacks an encoded signal sequence, was unchanged by the addition of microsomal membranes. These data indicated the presence of a functional signal sequence. (B) *In vitro* translation in the presence or absence of proteinase K. Protease treatment resulted in complete proteolysis of the 18 kD primary translation product, while the 16 kD processed form was unaffected.
- Permeabilization of the microsome with 0.1% TRITON-X100 rendered the processed form protease sensitive. These results indicate that the product had translated into the lumen of the microsome.

- FIGURE 20.** (A) The sequence of the human *ob* gene (SEQ ID NO:22). (B) A schematic diagram of the murine *ob* gene. (C) A schematic diagram of the human *ob* gene. In both (B) and (C), the start and stop codons are underlined. There is no evidence of a first intron homologous to the mouse first intron in the human gene, but its existence cannot be excluded.

- FIGURE 21** presents a schematic drawing of one of the cloning strategies employed to achieve recombinant expression of *ob* in pichia yeast. (A) Expression vector of *ob* with an α -mating factor signal sequence. (B) Schematic drawing of the structure of the recombinant fusion protein, including the amino acid sequence (SEQ ID NO:23) showing the *Xho*I site and putative KEX-2 and STE-13 cleavage sites, and the N-terminal surplus amino acids present after KEX-2 cleavage (SEQ ID NO:24). (C) An alternative strategy for producing mature *ob* under involves preparing a construct with an amino acid sequence corresponding to a *Xho*I cleavage site and a KEX-2 cleavage site immediately upstream of the mature *ob* polypeptide sequence (SEQ ID NO:25).

FIGURE 22 Alternative expression strategy in pichia. (A) Expression vector of an *ob* fusion with a His tag adopted from the pET expression system under control of the α -mating factor signal sequence. (B) Schematic drawing of the structure of the recombinant *ob* fusion protein containing a His tag, which includes the α -

5 mating factor signal sequence, putative KEX-2 and STE-13 cleavage sites, the His-tag, and a thrombin cleavage site, and which would yield *ob* with three surplus N-terminal amino acid residues.

FIGURE 23. (A) PAGE analysis of expression of murine *ob* (both the microheterogenous forms, *i.e.*, containing and missing Gln 49) in transformed

10 pichia yeast. The expected band of approximately 16 kD is visible in the transformed yeast culture fluid (second and third lanes), but not in culture fluid from non-transformed yeast (first lane). (B) PAGE analysis of partially purified recombinant *ob* polypeptide on carboxymethyl cellulose, a weak cation exchanger. A band of about 16 kD is very visible in fractions 3 and 4 from the column, which

15 was eluted with 250 mM NaCl. Lane 1 -- loaded sample; lane 2 -- flow through; lanes 3-5 -- fractions eluted with 250 mM NaCl.

THE REMAINDER OF THIS PAGE IS INTENTIONALLY LEFT BLANK

09635854.081000

Figure 24. The *ob* Protein Circulates in Mouse Plasma

24 A. Immunoprecipitations from Mouse Blood

.5 ml of mouse plasma was pre-cleared with unconjugated sepharose and incubated overnight with immunopurified anti-*ob* antibodies conjugated to sepharose 4B beads. The immunoprecipitate was separated on a 15% SDS-PAGE gel, transferred and Western blotted with an anti-*ob* antibody. The protein migrated with a molecular weight of ~16 kD, to the same position as the mature mouse *ob* protein expressed in yeast. The protein was absent in plasma from C57BL/6J *ob/ob* mice and increased ten-fold in plasma from C57BLB/Ks *db/db* mice relative to wild type mice. *db* mice have been suggested to overproduce the *ob* protein, secondary to resistance to its effects.

24 B. Increased Levels of *ob* in fatty rats

The fatty rat is obese as a result of a recessive mutation on rat chromosome 5. Genetic data has suggested a defect in the same gene as is mutant in *db* mice. Plasma from fatty rats and lean littermates was immunoprecipitated and run on Western blots. A twenty-fold increase in the circulating level of *ob* is seen in the mutant animals.

24 C. Quantitation of the *ob* Protein in Mouse Plasma

Increasing amounts of the recombinant mouse protein were added to 100 λ of plasma from *ob* mice and immunoprecipitated. The signal intensity on Western blots was compared to that from 100 λ of plasma from wild type mice. A linear increase in signal intensity was seen with increasing amounts of recombinant protein demonstrating that the immunoprecipitations were performed under conditions of antibody excess. Similar signals were seen in the wild type plasma sample and the sample with 2 ng of recombinant protein indicating the circulating level in mouse plasma is ~20 ng/ml.

24 D. *ob* Protein in Adipose Tissue Extracts

Cytoplasmic extracts of mouse adipose tissue were prepared from *db* and wild type mice. Western blots showed increased levels of the 16 kD protein in extracts prepared from *db* mice.

000T80"4985E960

Figure 25 The *ob* Protein Circulates at Variable Levels in Human Plasma

25A. Western Blots of Human Plasma

Plasma samples were obtained from six lean volunteers. Immunoprecipitation and Western blotting revealed the presence of an immunoreactive 16 kD protein, identical in size to a recombinant 146 amino acid human protein expressed in yeast. Variable levels of the protein were seen in each of the six samples.

25B. An ELISA (Enzyme Linked Immunoassay) for Human *ob*

Microtiter plates were coated with immunopurified anti-human *ob* antibodies. Known amounts of recombinant protein were added to the plates and detected using immunopurified biotinylated anti-*ob* antibodies. The resulting standard curve showed that the assay was capable of detecting 1 ng/ml or more of the human *ob* protein.

25.C. Quantitation of the *ob* Protein in Human Plasma

An ELISA immunoassay was performed using 100 λ of plasma from the six lean volunteers and the standards used in panel B. Levels of the *ob* protein ranging from 2 ng/ml in HP1 to 15 ng/ml in HP6 were seen. These data correlated with the Western blot data in panel A.

Figure 26 The *ob* Protein Forms Inter- or Intramolecular Disulphide Bonds

26 A. Western blots Under Non Reducing Conditions

The Western blots of mouse and human plasma were repeated with and without the addition of reducing agents to the sample buffer. When β -Mercaptoethanol is omitted from the sample buffer, immunoprecipitates from *db* plasma migrate with an apparent molecular mass of 16 kD and 32 kD. Addition of β -Mercaptoethanol to the buffer leads to the disappearance of the 32 kD moiety (see Fig. 1). This result is recapitulated when the mouse protein is expressed in the yeast, *Pichia pastoris*. In this case, the mouse *ob* protein migrates to the position of a dimer. Under reducing conditions the purified

recombinant mouse protein migrates with an apparent molecular weight of 16 kD indicating that the 32 kD molecular form is the result of one or two intermolecular disulphide bonds. The human protein expressed *in vivo* and in *Pichia pastoris* migrates with a molecular mass of 16 kD under both conditions (data not shown).

26B. The Human Protein Expressed in Yeast Contains an Intramolecular Disulphide Bond

Secreted proteins generally assume their correct conformation when expressed in the *Pichia pastoris* expression system. The 146 amino acid mature human protein was expressed in *Pichia pastoris* and purified from the yeast media by a two-step purification protocol involving IMAC and gel filtration. The purified recombinant protein was subjected to mass spectrometry before and after cyanogen bromide cleavage. Cyanogen bromide cleaves at the carboxy terminus of methionine residues. The molecular mass of the recombinant yeast protein was $16,024 \pm 3$ Da (calculated molecular mass = 16,024 Da). Cyanogen bromide cleaves after the three methionines in the protein sequence at amino acids 75, 89 and 157. The cyanogen bromide fragment with measured mass 8435.6 Da corresponds to amino acids 90-157 and 158-167 joined by a disulphide linkage between cys-117 and cys-167 (calculated molecular mass = 8434.5 Da).

Figure 27 Preparation of Bioactive Recombinant Protein

The nucleotide sequence corresponding to the 145 amino acid mature mouse *ob* protein was cloned into the PET 15b expression vector. This PET vector inserts a polyhistidine tract (His-tag) upstream of the cloned sequence which allows efficient purification using Immobilized Metal Affinity Chromatography (IMAC). The recombinant bacterial protein initially partitioned in the insoluble membrane fraction after bacterial lysis. The membrane fraction was solubilized using guanidium hydrochloride and loaded onto an IMAC column. The protein was eluted stepwise with increasing concentrations of imidazole as shown. The eluted protein was refolded and treated with thrombin to remove the His-tag, as described below. The final yield of soluble protein was 45 ng/ml of bacterial culture.

Figure 2B Biologic Effects of the *ob* Protein

Fig. 2BA. Time Course of Food Intake and Body Weight

Groups of ten animals received either daily intraperitoneal injections of the *ob* protein at a dose of 5 µg/kg/day, daily injections of PBS or no treatment. The treatment groups included C57Bl/6J *ob/ob* mice (left panels), C57Bl/Ks *db/db* mice (center panels) and CBA/J+/+ mice (right panels). The food intake of the mice was measured daily and the body weight was recorded at three to four day intervals as indicated. (The scale of the body weight in grams is different for the wild type mice vs. the *ob* and *db* mice.) The food intake of the *ob* mice receiving protein was reduced after the first injection and stabilized after the fourth day at a level ~40% of that seen in the sham injected group ($p < .001$). The body weight of these animals decreased an average of 1.3 grams/day and stabilized after three weeks to a level ~60% of the starting weight ($p < .0001$). No effect of the protein was demonstrable in *db* mice. Small but significant effects on body weight were observed in CBA/J mice at two early time points ($p < .02$). The standard error of each measure is depicted by a bar and the statistical significance of these results is shown in Table 1.

Fig. 2BB. Pair Feeding of *ob* Mice

A group of four C57Bl/6J *ob/ob* mice were fed an amount of food equal to that consumed by the group of *ob* mice receiving recombinant protein. The weight loss for both groups was calculated after five, eight and twelve days. The food restricted mice lost less weight than the *ob* mice receiving protein ($p < .02$). This result indicates that the weight reducing effect of the *ob* protein is the result of effects on both food intake and energy expenditure.

Fig. 2BC. Photograph of a Treated *ob* Mouse

Shown are two C57Bl/6J *ob/ob* mice. The mouse on the left received PBS and weighed 65 grams which was the starting weight. The mouse on the right received daily injections of the recombinant *ob* protein. The starting weight of this animal was also 65 grams, and the weight after three weeks of protein treatment was 38 grams.

00635864-081000

Fig. 2D. Livers From Treated and Untreated *ob* Mice

Shown are livers from treated and untreated C57Bl/6J ob/ob mice. The liver from the mouse receiving PBS had the gross appearance of a fatty liver and weighed 5.04 grams. The liver from the mouse receiving the recombinant *ob* protein had a normal appearance and weighed 2.23 grams.

Figure 29 InSitu Hybridization of *ob* to Adipose Tissue

Sense and Antisense *ob* RNA was labeled in vitro using Sp6 and T7 polymerase and digoxigenin. The labeled RNAs were hybridized to paraffin embedded sections of adipose tissue from epididymal fat pads of eight week old C57Bl/Ks mice (labelled wild type) and C57Bl/Ks db/db mice (labelled db). In the figure, the lipid droplets appear as unstained vacuoles within cells. The cytoplasm is a thin rim at the periphery of the cells and is indistinguishable from the cell membrane X 65. Hybridization to all the adipocytes in the field was detected in the wild type sections only using the antisense probe and greatly increased levels were seen in the tissue sections from the db/db animals.

Figure 30 ob RNA Is Expressed in Adipocytes *in vivo* and *in vitro*

Total RNA (10 micrograms) from several different sources was electrophoresed on Northern blots and hybridized to an *ob* probe. Firstly, differences in cell buoyancy after collagenase digestion was used to purify adipocytes. *ob* RNA was present only in the adipocyte fraction. (lane SV indicates the stromovascular fraction and A indicates the adipocyte fraction) in addition, *ob* RNA was not expressed in the undifferentiated 3T3-442 preadipocyte cells. (labelled U) Differentiated adipocytes from these cell lines expressed clearly detectable levels of *ob* mRNA (labelled D).

Figure 31 ob RNA is Expressed in All Adipose Tissue Depots

All of the adipose tissue depots tested expressed *ob* RNA. The inguinal fat pad expressed somewhat lower RNA levels although there was variability in the levels of signals in different experiments. (Fig.31A) Lanes 1) epididymal 2) inguinal 3) abdominal 4) parametrial fat pads. Brown fat also expressed a low level of *ob* RNA. (Fig.31B) The level of *ob* expression in brown fat was unchanged in animals housed at 4°C for one week while the abundance of the brown fat specific UCP RNA, known to be cold inducible, increased five-fold.

Figure 32 Expression of ob RNA in db/db and Gold ThioGlucose Treated Mice

Total RNA from the parametrial fat pads of db/db and Gold Thioglucose (GTG) treated mice was electrophoresed on a Northern blot. GTG administered as a single dose is known to cause obesity by inducing specific hypothalamic lesions. One month old CBA female mice were treated with GTG (.2 mg/g) with a resulting increase of >20 g in treated animals relative to control animals (<5 g). Hybridization of an *ob* probe to RNA from db/db and GTG treated mice revealed a twenty-fold increase in the abundance of *ob* RNA relative to control RNA (actin or GAPDH).

09635864-081000

Figure 33 Northern blot analysis of human RNA. Northern blots containing 10 μ g of total RNA from human adipose tissue (FAT, panel A) and 2 μ g of polyA⁺ RNA from other human tissues (panel B) were hybridized to human OB or human β actin probes as indicated. An intense signal at ~4.5 kb was seen with the adipose tissue total RNA. Hybridization to the polyA⁺ RNA revealed detectable signals in heart (HE) and placenta (PL), whereas OB RNA was not detected in brain (BR), lung (LU), liver (LI), skeletal muscle (SM), kidney (KI), and pancreas (PA). In each case, the length of the autoradiographic exposure is indicated. Of note, the genesis of the lower molecular bands seen in placental RNA (e.g., alternate splicing, RNA degradation) is not known.

Figure 34 YAC contig containing the human OB gene and 8 microsatellite markers. The YAC-based STS-content map of the region of chromosome 7 containing the human OB gene is depicted, as deduced by SEGMAP/Version 3.29 (Green and Green, 1991a; C.L. Magness and P. Green, unpublished data). The 19 uniquely-ordered STSs (see Table 1) are listed along the top. The 8 microsatellite-specific STSs are indicated with stars (see Table 2). Also indicated are the STSs corresponding to the PAX4 and OB genes as well as the predicted positions of the centromere (CEN) and 7q telomere (TEL) relative to the contig. Each of the 43 YAC clones is depicted by a horizontal bar, with its name given to the left and estimated YAC size (in kb, measured by pulsed-field gel electrophoresis) provided in parenthesis. The presence of an STS in a YAC is indicated by a darkened circle at the appropriate position. When an STS corresponds to the insert end of a YAC, a square is placed around the corresponding circle, both along the top (near the STS name) and at the end of the YAC from which it was derived. For the 5 YACs at the bottom (below the horizontal dashed line), 1 or more STS(s) expected to be present (based on the established STS order) was not detected [as assessed by testing the individual YACs with the corresponding STS-specific

PCR assay(s) at least twice], and these are depicted as open circles at the appropriate positions. Most of the YACs were isolated from a human-hamster hybrid cell-derived library (Green et al. 1995a), with their original names as indicated. The remaining YACs were isolated from total human genomic libraries, and their original library locations are provided in Table 3.

Boxes are placed around the names of the 3 YACs (yWSS691, yWSS999, and yWSS2935) that were found by FISH analysis to map to 7q31.3.

The contig is displayed in its uncomputed form, where YAC sizes are not used to estimate clone overlaps or STS spacing, and all of the STSs are therefore spaced in an equidistant fashion. In the computed form, where YAC sizes are used to estimate the relative distance separating each pair of adjacent STSs as well as the extent of clone overlaps, the total YAC contig appears to span just over 2 Mb.

THE REMAINDER OF THIS PAGE IS INTENTIONALLY LEFT BLANK

09635864.081000

DETAILED DESCRIPTION

In accordance with the present invention there may be employed conventional molecular biology, microbiology, and recombinant DNA techniques within the skill of the art. Such techniques are explained fully in the literature. See, e.g.,

5 Sambrook, Fritsch & Maniatis, *Molecular Cloning: A Laboratory Manual*, Second Edition (1989) Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York (herein "Sambrook et al., 1989"); *DNA Cloning: A Practical Approach*, Volumes I and II (D.N. Glover ed. 1985); *Oligonucleotide Synthesis* (M.J. Gait ed. 1984); *Nucleic Acid Hybridization* [B.D. Hames & S.J. Higgins eds. (1985)];

10 *Transcription And Translation* [B.D. Hames & S.J. Higgins, eds. (1984)]; *Animal Cell Culture* [R.I. Freshney, ed. (1986)]; *Immobilized Cells And Enzymes* [IRL Press, (1986)]; B. Perbal, *A Practical Guide To Molecular Cloning* (1984). Of particular relevance to the present invention are strategies for isolating, cloning, sequencing, analyzing, and characterizing a gene or nucleic acid based on the well

15 known polymerase chain reaction (PCR) techniques.

Therefore, if appearing herein, the following terms shall have the definitions set out below.

The term "body weight modulator", "modulator", "modulators", and any variants not specifically listed, may be used herein interchangeably, and as used throughout

20 the present application and claims refers in one instance to both nucleotides and to proteinaceous material, the latter including both single or multiple proteins. More specifically, the aforementioned terms extend to the nucleotides and to the DNA having the sequences described herein and presented in Figure 1 (SEQ ID NO:1), and Figure 2 (SEQ ID NO:3). Likewise, the proteins having the amino acid

25 sequence data described herein and presented in Figure 1 (SEQ ID NO:2), and Figure 3 (SEQ ID NO:4) are likewise contemplated, as are the profile of activities set forth with respect to all materials both herein and in the claims. Accordingly, nucleotides displaying substantially equivalent or altered activity are likewise

5

10

A "replicon" is any genetic element (e.g., plasmid, chromosome, virus) that functions as an autonomous unit of DNA replication *in vivo*, *i.e.*, capable of replication under its own control.

15

20

"Heterologous" DNA refers to DNA not naturally located in the cell, or in a chromosomal site of the cell. Preferably, the heterologous DNA includes a gene foreign to the cell.

25

or heterologous DNA when the transfected DNA effects a phenotypic change. Preferably, the transforming DNA should be integrated (covalently linked) into chromosomal DNA making up the genome of the cell.

5 A "clone" is a population of cells derived from a single cell or common ancestor by mitosis.

10 A "nucleic acid molecule" refers to the phosphate ester polymeric form of ribonucleosides (adenosine, guanosine, uridine or cytidine; "RNA molecules") or deoxyribonucleosides (deoxyadenosine, deoxyguanosine, deoxythymidine, or deoxycytidine; "DNA molecules") in either single stranded form, or a double-
 15 stranded helix. Double stranded DNA-DNA, DNA-RNA and RNA-RNA helices are possible. The term nucleic acid molecule, and in particular DNA or RNA molecule, refers only to the primary and secondary structure of the molecule, and does not limit it to any particular tertiary or quaternary forms. Thus, this term includes double-stranded DNA found, *inter alia*, in linear or circular DNA
 20 molecules (*e.g.*, restriction fragments), plasmids, and chromosomes. In discussing the structure of particular double-stranded DNA molecules, sequences may be described herein according to the normal convention of giving only the sequence in the 5' to 3' direction along the nontranscribed strand of DNA (*i.e.*, the strand having a sequence homologous to the mRNA). A "recombinant DNA molecule" is a DNA molecule that has undergone a molecular biological manipulation.

A nucleic acid molecule is "hybridizable" to another nucleic acid molecule, such as a cDNA, genomic DNA, or RNA, when a single stranded form of the nucleic acid molecule can anneal to the other nucleic acid molecule under the appropriate conditions of temperature and solution ionic strength (*see* Sambrook et al., *supra*).
 25 The conditions of temperature and ionic strength determine the "stringency" of the hybridization. For preliminary screening for homologous nucleic acids, low stringency hybridization conditions, corresponding to a T_m of 55°, can be used, *e.g.*, 5x SSC, 0.1% SDS, 0.25% milk, and no formamide; or 30% formamide, 5x

- SSC, 0.5% SDS). Moderate stringency hybridization conditions correspond to a higher T_m , *e.g.*, 40% formamide, with 5x or 6x SCC. High stringency hybridization conditions correspond to the highest T_m , *e.g.*, 50% formamide, 5x or 6x SCC. Hybridization requires that the two nucleic acids contain complementary sequences, although depending on the stringency of the hybridization, mismatches between bases are possible. The appropriate stringency for hybridizing nucleic acids depends on the length of the nucleic acids and the degree of complementation, variables well known in the art. The greater the degree of similarity or homology between two nucleotide sequences, the greater the value of T_m for hybrids of nucleic acids having those sequences. The relative stability (corresponding to higher T_m) of nucleic acid hybridizations decreases in the following order: RNA:RNA, DNA:RNA, DNA:DNA. For hybrids of greater than 100 nucleotides in length, equations for calculating T_m have been derived (*see* Sambrook et al., *supra*, 9.50-0.51). For hybridization with shorter nucleic acids, *i.e.*, oligonucleotides, the position of mismatches becomes more important, and the length of the oligonucleotide determines its specificity (*see* Sambrook et al., *supra*, 11.7-11.8). Preferably a minimum length for a hybridizable nucleic acid is at least about 10 nucleotides; more preferably at least about 15 nucleotides; most preferably the length is at least about 20 nucleotides.
- "Homologous recombination" refers to the insertion of a foreign DNA sequence of a vector in a chromosome. Preferably, the vector targets a specific chromosomal site for homologous recombination. For specific homologous recombination, the vector will contain sufficiently long regions of homology to sequences of the chromosome to allow complementary binding and incorporation of the vector into the chromosome. Longer regions of homology, and greater degrees of sequence similarity, may increase the efficiency of homologous recombination.

A DNA "coding sequence" is a double-stranded DNA sequence which is transcribed and translated into a polypeptide in a cell *in vitro* or *in vivo* when placed under the control of appropriate regulatory sequences. The boundaries of

5

10

15

20

25

5

10

W

20

25

An "antibody" is any immunoglobulin, including antibodies and fragments thereof, that binds a specific epitope. The term encompasses polyclonal, monoclonal, and chimeric antibodies, the last mentioned described in further detail in U.S. Patent Nos. 4,816,397 and 4,816,567, as well as antigen binding portions of antibodies, including Fab, F(ab')₂ and Fr (including single chain antibodies). Accordingly, the phrase "antibody molecule" in its various grammatical forms as used herein contemplates both an intact immunoglobulin molecule and an immunologically active portion of an immunoglobulin molecule containing the antibody combining site. An "antibody combining site" is that structural portion of an antibody molecule comprised of heavy and light chain variable and hypervariable regions that specifically binds antigen.

Exemplary antibody molecules are intact immunoglobulin molecules, substantially intact immunoglobulin molecules and those portions of an immunoglobulin molecule that contains the paratope, including those portions known in the art as Fab, Fab', F(ab')₂ and F(v), which portions are preferred for use in the therapeutic methods described herein.

Fab and F(ab')₂ portions of antibody molecules are prepared by the proteolytic reaction of papain and pepsin, respectively, on substantially intact antibody molecules by methods that are well-known. See for example, U.S. Patent No. 4,342,566 to Theofilopolous et al. Fab' antibody molecule portions are also well-known and are produced from F(ab')₂ portions followed by reduction of the disulfide bonds linking the two heavy chain portions as with mercaptoethanol, and followed by alkylation of the resulting protein mercaptan with a reagent such as iodoacetamide. An antibody containing intact antibody molecules is preferred herein.

The phrase "monoclonal antibody" in its various grammatical forms refers to an antibody having only one species of antibody combining site capable of immunoreacting with a particular antigen. A monoclonal antibody thus typically

displays a single binding affinity for any antigen with which it immunoreacts. A monoclonal antibody may therefore contain an antibody molecule having a plurality of antibody combining sites, each immunospecific for a different antigen; e.g., a bispecific (chimeric) monoclonal antibody.

- 5 A composition comprising "A" (where "A" is a single protein, DNA molecule, vector, recombinant host cell, etc.) is substantially free of "B" (where "B" comprises one or more contaminating proteins, DNA molecules, vectors, etc., but excluding racemic forms of A) when at least about 75% by weight of the proteins, DNA, vectors (depending on the category of species to which A and B belong) in
10 the composition is "A". Preferably, "A" comprises at least about 90% by weight of the A+B species in the composition, most preferably at least about 99% by weight. It is also preferred that a composition, which is substantially free of contamination, contain only a single molecular weight species having the activity or characteristic of the species of interest.
- 15 The phrase "pharmaceutically acceptable" refers to molecular entities and compositions that are physiologically tolerable and do not typically produce an allergic or similar untoward reaction, such as gastric upset, dizziness and the like, when administered to a human. Preferably, as used herein, the term "pharmaceutically acceptable" means approved by a regulatory agency of the
20 Federal or a state government or listed in the U.S. Pharmacopeia or other generally recognized pharmacopeia for use in animals, and more particularly in humans. The term "carrier" refers to a diluent, adjuvant, excipient, or vehicle with which the compound is administered. Such pharmaceutical carriers can be sterile liquids, such as water and oils, including those of petroleum, animal,
25 vegetable or synthetic origin, such as peanut oil, soybean oil, mineral oil, sesame oil and the like. Water or aqueous solution saline solutions and aqueous dextrose and glycerol solutions are preferably employed as carriers, particularly for injectable solutions. Suitable pharmaceutical carriers are described in "Remington's Pharmaceutical Sciences" by E.W. Martin.

09635864, 081000

5 a therapeutically effective amount is sufficient to cause an improvement in a clinically significant condition in the host.

enhances the immune response (Hood et al., *Immunology, Second Ed.*, 1984, Benjamin/Cummings: Menlo Park, California, p. 384). Often, a primary challenge with an antigen alone, in the absence of an adjuvant, will fail to elicit a humoral or cellular immune response. Adjuvants include, but are not limited to, complete Freund's adjuvant, incomplete Freund's adjuvant, saponin, mineral gels such as aluminum hydroxide, surface active substances such as lysolecithin, pluronic polyols, polyanions, peptides, oil or hydrocarbon emulsions, keyhole limpet hemocyanins, dinitrophenol, and potentially useful human adjuvants such as BCG (*bacille Calmette-Guerin*) and *Corynebacterium parvum*. Preferably, the adjuvant is pharmaceutically acceptable.

20 In its primary aspect, the present invention is directed to the identification of materials that function as modulators of mammalian body weight. In particular, the invention concerns the isolation, purification and sequencing of certain nucleic acids that correspond to the *ob* gene in both mice and humans, as well as the corresponding polypeptides expressed by these nucleic acids. The invention thus
25 comprises the discovery of nucleic acids having the nucleotide sequences set forth in FIGURE 1 (SEQ ID NO:1) and FIGURE 2 (SEQ ID NO:3), and to degenerate variants, alleles and fragments thereof, all possessing the activity of modulating body weight and adiposity. The correspondence of the present nucleic acids to the *ob* gene portends their significant impact on conditions such as obesity as well as

In particular, the present invention contemplates that naturally occurring fragments of the ob polypeptide may be important. The peptide sequence includes a number of sites that are frequently the target for proteolytic cleavage, *e.g.*, arginine residues. It is possible that the full length polypeptide may be cleaved at one or more such sites to form biologically active fragments. Such biologically active fragments may either agonize or antagonize the functional activity of the ob polypeptide to reduce body weight.

Also, antibodies including both polyclonal and monoclonal antibodies, and drugs that modulate the production or activity of the weight control modulators recognition factors and/or their subunits may possess certain diagnostic

applications and may for example, be utilized for the purpose of detecting and/or measuring conditions where abnormalities in body weight are or may be likely to develop. For example, the modulator peptides or their active fragments may be used to produce both polyclonal and monoclonal antibodies to themselves in a

5 variety of cellular media, by known techniques such as the hybridoma technique utilizing, for example, fused mouse spleen lymphocytes and myeloma cells. These techniques are described in detail below. Likewise, small molecules that mimic or antagonize the activity(ies) of the receptor recognition factors of the invention may be discovered or synthesized, and may be used in diagnostic and/or therapeutic

10 protocols.

Panels of monoclonal antibodies produced against modulator peptides can be screened for various properties; i.e., isotype, epitope, affinity, etc. Of particular interest are monoclonal antibodies that neutralize the activity of the modulator peptides. Such monoclonals can be readily identified in activity assays for the

15 weight modulators. High affinity antibodies are also useful when immunoaffinity purification of native or recombinant modulator is possible.

Preferably, the anti-modulator antibody used in the diagnostic and therapeutic methods of this invention is an affinity purified polyclonal antibody. More preferably, the antibody is a monoclonal antibody (mAb). In addition, it is

20 preferable for the anti-modulator antibody molecules used herein be in the form of Fab, Fab', F(ab')₂ or F(v) portions of whole antibody molecules.

As suggested earlier, a diagnostic method useful in the present invention comprises examining a cellular sample or medium by means of an assay including an effective amount of an antagonist to a modulator protein, such as an anti-

25 modulator antibody, preferably an affinity-purified polyclonal antibody, and more preferably a mAb. In addition, it is preferable for the anti-modulator antibody molecules used herein be in the form of Fab, Fab', F(ab')₂ or F(v) portions or whole antibody molecules. As previously discussed, patients capable of benefiting

09635864-081000

from this method include those suffering from cancer, AIDS, obesity or other condition where abnormal body weight is a characteristic or factor. Methods for isolating the modulator and inducing anti-modulator antibodies and for determining and optimizing the ability of anti-modulator antibodies to assist in the examination
5 of the target cells are all well-known in the art.

The nucleic acids contemplated by the present invention extend as indicated, to other nucleic acids that code on expression for peptides such as those set forth in FIGURE 1 (SEQ ID NO:2), FIGURE 3 (SEQ ID NO:4), FIGURE 5 (SEQ ID NO:5), and FIGURE 6 (SEQ ID NO:6) herein. Accordingly, while specific DNA
10 has been isolated and sequenced in relation to the *ob* gene, any animal cell potentially can serve as the nucleic acid source for the molecular cloning of a gene encoding the peptides of the invention. The DNA may be obtained by standard procedures known in the art from cloned DNA (*e.g.*, a DNA "library"), by chemical synthesis, by cDNA cloning, or by the cloning of genomic DNA, or
15 fragments thereof, purified from the desired cell (See, for example, Sambrook et al., 1989, *supra*; Glover, D.M. (ed.), 1985, DNA Cloning: A Practical Approach, MRL Press, Ltd., Oxford, U.K. Vol. I, II). Clones derived from genomic DNA may contain regulatory and intron DNA regions in addition to coding regions; clones derived from cDNA will not contain intron sequences. Whatever the
20 source, the gene should be molecularly cloned into a suitable vector for propagation of the gene.

In the molecular cloning of the gene from genomic DNA, the genomic DNA can be amplified using primers selected from the cDNA sequences. Alternatively, DNA fragments are generated, some of which will encode the desired gene. The
25 DNA may be cleaved at specific sites using various restriction enzymes. One may also use DNase in the presence of manganese to fragment the DNA, or the DNA can be physically sheared, as for example, by sonication. The linear DNA fragments can then be separated according to size by standard techniques,

including but not limited to, agarose and polyacrylamide gel electrophoresis and column chromatography.

Once the DNA fragments are generated, identification of the specific DNA fragment containing the desired *ob* or *ob*-like gene may be accomplished in a number of ways. For example, if an amount of a portion of a *ob* or *ob*-like gene or its specific RNA, or a fragment thereof, is available and can be purified and labeled, the generated DNA fragments may be screened by nucleic acid hybridization to the labeled probe (Benton and Davis, 1977, *Science* 196:180; Grunstein and Hogness, 1975, *Proc. Natl. Acad. Sci. U.S.A.* 72:3961). The present invention provides such nucleic acid probes, which can be conveniently prepared from the specific sequences disclosed herein, *e.g.*, a hybridizable probe having a nucleotide sequence corresponding to at least a 10, and preferably a 15, nucleotide fragment of the sequences depicted in Figure 1 (SEQ ID NO:1) or Figure 2 (SEQ ID NO:3). Preferably, a fragment is selected that is highly unique to the modulator peptides of the invention. Those DNA fragments with substantial homology to the probe will hybridize. As noted above, the greater the degree of homology, the more stringent hybridization conditions can be used. In one embodiment, low stringency hybridization conditions are used to identify a homologous modulator peptide. However, in a preferred aspect, and as demonstrated experimentally herein, a nucleic acid encoding a modulator peptide of the invention will hybridize to a nucleic acid having a nucleotide sequence such as depicted in Figure 1 (SEQ ID NO:1) or Figure 2 (SEQ ID NO:3), or a hybridizable fragment thereof, under moderately stringent conditions; more preferably, it will hybridize under high stringency conditions.

Alternatively, the presence of the gene may be detected by assays based on the physical, chemical, or immunological properties of its expressed product. For example, cDNA clones, or DNA clones which hybrid-select the proper mRNAs, can be selected which produce a protein that, *e.g.*, has similar or identical electrophoretic migration, isoelectric focusing behavior, proteolytic digestion

- A wide variety of host/expression vector combinations may be employed in expressing the DNA sequences of this invention. Useful expression vectors, for example, may consist of segments of chromosomal, non-chromosomal and Synthetic DNA sequences. Suitable vectors include derivatives of SV40 and
- 5 known bacterial plasmids, e.g., *E. coli* plasmids col El, pCR1, pBR322, pMB9, pUC or pUC plasmid derivatives, e.g., pGEX vectors, pET vectors, pmal-c, pFLAG, etc., and their derivatives, plasmids such as RP4; phage DNAs, e.g., the numerous derivatives of phage λ , e.g., NM989, and other phage DNA, e.g., M13 and Filamentous single stranded phage DNA; yeast plasmids such as the 2 μ
- 10 plasmid or derivatives thereof; vectors useful in eukaryotic cells, such as vectors useful in insect or mammalian cells; vectors derived from combinations of plasmids and phage DNAs, such as plasmids that have been modified to employ phage DNA or other expression control sequences; and the like. In a preferred embodiment, expression of *ob* is achieved in methylotrophic yeast, e.g., *Pichia*
- 15 *pastoris* yeast (see, e.g., International Patent Publication No. WO 90/03431, published 5 April 1990, by Brierley et al.; International Patent Publication No. WO 90/10697, published 20 September 1990, by Siegel et al.). In a specific embodiment, *infra*, an expression vector is engineered for expression of *ob* under control of the α -mating factor signal sequence.
- 20 Any of a wide variety of expression control sequences -- sequences that control the expression of a DNA sequence operatively linked to it -- may be used in these vectors to express the DNA sequences of this invention. Such useful expression control sequences include, for example, the early or late promoters of SV40, CMV, vaccinia, polyoma or adenovirus, the *lac* system, the *trp* system, the *TAC*
- 25 system, the *TRC* system, the *LTR* system, the major operator and promoter regions of phage λ , the control regions of fd coat protein, the promoter for 3-phosphoglycerate kinase or other glycolytic enzymes, the promoters of acid phosphatase (e.g., Pho5), the AOX 1 promoter of methylotrophic yeast, the promoters of the yeast α -mating factors, and other sequences known to control the

09635864-081000

expression of genes of prokaryotic or eukaryotic cells or their viruses, and various combinations thereof.

A wide variety of unicellular host cells are also useful in expressing the DNA sequences of this invention. These hosts may include well known eukaryotic and prokaryotic hosts, such as strains of *E. coli*, *Pseudomonas*, *Bacillus*, *Streptomyces*; fungi such as yeasts (*Saccharomyces*, and methylotrophic yeast such as *Pichia*, *Candida*, *Hansenula*, and *Torulopsis*); and animal cells, such as CHO, R1.1, B-W and L-M cells, African Green Monkey kidney cells (e.g., COS 1, COS 7, BSC1, BSC40, and BMT10), insect cells (e.g., Sf9), and human cells and plant cells in tissue culture.

It will be understood that not all vectors, expression control sequences and hosts will function equally well to express the DNA sequences of this invention. Neither will all hosts function equally well with the same expression system. However, one skilled in the art will be able to select the proper vectors, expression control sequences, and hosts without undue experimentation to accomplish the desired expression without departing from the scope of this invention. For example, in selecting a vector, the host must be considered because the vector must function in it. The vector's copy number, the ability to control that copy number, and the expression of any other proteins encoded by the vector, such as antibiotic markers, will also be considered.

In selecting an expression control sequence, a variety of factors will normally be considered. These include, for example, the relative strength of the system, its controllability, and its compatibility with the particular DNA sequence or gene to be expressed, particularly as regards potential secondary structures. Suitable unicellular hosts will be selected by consideration of, e.g., their compatibility with the chosen vector, their secretion characteristics, their ability to fold proteins correctly, and their fermentation requirements, as well as the toxicity to the host

Considering these and other factors a person skilled in the art will be able to construct a variety of vector/expression control sequence/host combinations that will express the DNA sequences of this invention on fermentation or in large scale animal culture.

10 The non-ob sequences can be amino- or carboxy-terminal to the ob sequences. More preferably, for stable expression of a proteolytically inactive ob fusion protein, the portion of the non-ob fusion protein is joined via a peptide bond to the amino terminus of the ob protein. A recombinant DNA molecule encoding such a fusion protein comprises a sequence encoding at least a functionally active portion
15 of a non-ob protein joined in-frame to the ob coding sequence, and preferably encodes a cleavage site for a specific protease, *e.g.*, thrombin or Factor Xa, preferably at the ob-non-ob juncture. In a specific embodiment, the fusion protein is expressed in *Escherichia coli* or in *P. pastoris*.

In a specific embodiment, *infra*, vectors were prepared to express the murine and human *ob* genes, with and without the codon for gln-49, in bacterial expression systems and yeast (*Pichia*) expression systems as fusion proteins. The *ob* gene is prepared with an endonuclease cleavage site, *e.g.*, using PCR and novel primers. It is desirable to confirm sequences generated by PCR, since the probability of including a point mutation is greater with this technique. A plasmid containing a histidine tag (HIS-TAG) and a proteolytic cleavage site is used. The presence of the histidine makes possible the selective isolation of recombinant proteins on a Ni-chelation column, or by affinity purification. The proteolytic cleavage site, in a specific embodiment, *infra*, a thrombin cleavage site, is engineered so that

treatment with the protease, *e.g.*, thrombin, will release the full length mature (*i.e.*, lacking a signal sequence) ob polypeptide.

In another aspect, the pGEX vector (Smith and Johnson, 1988, Gene 67:31-40) can be used. This vector fuses the schistosoma japonicum glutathionine S-

5 transferase cDNA to the sequence of interest. Bacterial proteins are harvested and recombinant proteins can be quickly purified on a reduced glutathione affinity column. The GST carrier can subsequently be cleaved from fusion proteins by digestion with site-specific proteases. After cleavage, the carrier and uncleaved fusion protein can be removed by absorption on glutathione agarose. Difficulty
10 with the system occasionally arises when the encoded protein is insoluble in aqueous solutions.

Expression of recombinant proteins in bacterial systems may result in incorrect folding of the expressed protein, requiring refolding. The recombinant protein can be refolded prior to or after cleavage to form a functionally active ob polypeptide.

15 The ob polypeptide may be refolded by the steps of (i) incubating the protein in a denaturing buffer that contains a reducing agent, and then (ii) incubating the protein in a buffer that contains an oxidizing agent, and preferably also contains a protein stabilizing agent or a chaotropic agent, or both. Suitable redox (reducing/oxidizing) agent pairs include, but are not limited to, reduced glutathione/glutathione disulfide, cystine/cysteine, cystamine/cysteamine, and 2-mercaptoethanol/2-hydroxyethyl disulfide. In a particular aspect, the fusion protein can be solubilized in a denaturant, such as urea, prior to exchange into the reducing buffer. In preferred embodiment, the protein is also purified, *e.g.*, by ion exchange or Ni-chelation chromatography, prior to exchange into the reducing buffer. Denaturing agents include but are not limited to urea and guanidine-HCl. The recombinant protein is then diluted about at least 10-fold, more preferably about 100-fold, into an oxidizing buffer that contains an oxidizing agent, such as but not limited to 0.1 M Tris-HCl, pH 8.0, 1 mM EDTA, 0.15 M NaCl, 0.3 M oxidized glutathione. The fusion protein is then incubated for about 1 to about 24

hours, preferably about 2 to about 16 hours, at room temperature in the oxidizing buffer. The oxidizing buffer may comprise a protein stabilizing agent, *e.g.*, a sugar, an alcohol, or ammonium sulfate. The oxidizing buffer may further comprises a chaotropic agent at low concentration, to destabilize incorrect

5 intermolecular interactions and thus promote proper folding. Suitable chaotropic agents include but are not limited to a detergent, a polyol, L-arginine, guanidine-HCl and polyethylene glycol (PEG). It is important to use a low enough concentration of the chaotropic agent to avoid denaturing the protein. The refolded protein can be concentrated by at least about 10-fold, more preferably by

10 the amount it was diluted into the oxidizing buffer.

Bacterial fermentation processes can also result in a recombinant protein preparation that contains unacceptable levels of endotoxins. Therefore, the invention contemplates removal of such endotoxins, *e.g.*, by using endotoxin-specific antibodies or other endotoxin binding molecules. The presence of

15 endotoxins can be determined by standard techniques, such as by employing E-TOXATE Reagents (Sigma), or with bioassays.

In addition to the specific example, the present inventors contemplate use of baculovirus, mammalian, and yeast expression systems to express the ob protein. For example, in baculovirus expression systems, both non-fusion transfer vectors,

20 such as but not limited to pVL941 (BamH1 cloning site; Summers), pVL1393 (BamH1, SmaI, XbaI, EcoRI, NotI, XmaIII, BglII, and PstI cloning site; Invitrogen), pVL1392 (BglII, PstI, NotI, XmaIII, EcoRI, XbaI, SmaI, and BamH1 cloning site; Summers and Invitrogen), and pBlueBacIII (BamH1, BglII, PstI, NcoI, and HindIII cloning site, with blue/white recombinant screening possible;

25 Invitrogen), and fusion transfer vectors, such as but not limited to pAc700 (BamH1 and KpnI cloning site, in which the BamH1 recognition site begins with the initiation codon; Summers), pAc701 and pAc702 (same as pAc700, with different reading frames), pAc360 (BamH1 cloning site 36 base pairs downstream of a polyhedrin initiation codon; Invitrogen(195)), and pBlueBacHisA, B, C (three

5 vectors with inducible promoters, such as dihydrofolate reductase (DHFR), *e.g.*,
any expression vector with a DHFR expression vector, or a DHFR/methotrexate
co-amplification vector, such as pED (PstI, SalI, SbaI, SmaI, and EcoRI cloning
site, with the vector expressing both the cloned gene and DHFR; *see* Kaufman,
Current Protocols in Molecular Biology, 16.12, 1991). Alternatively, a glutamine
10 synthetase/methionine sulfoximine co-amplification vector, such as pEE14
(HindIII, XbaI, SmaI, SmaI, EcoRI, and BclI cloning site, in which the vector
expresses glutamine synthase and the cloned gene; Celltech). In another
embodiment, a vector that directs episomal expression under control of Epstein
Barr Virus (EBV) can be used, such as pREP4 (BamHI, SfiI, XhoI, NotI, NheI,
15 HindIII, NheI, PvuII, and KpnI cloning site, constitutive RSV LTR promoter,
hygromycin selectable marker; Invitrogen), pCEP4 (BamHI, SfiI, XhoI, NotI,
NheI, HindIII, NheI, PvuII, and KpnI cloning site, constitutive hCMV immediate
early gene, hygromycin selectable marker; Invitrogen), pMEP4 (KpnI, PvuI,
NheI, HindIII, NotI, XhoI, SfiI, BamHI cloning site, inducible methallothionein
20 IIa gene promoter, hygromycin selectable marker: Invitrogen), pREP8 (BamHI,
XhoI, NotI, HindIII, NheI, and KpnI cloning site, RSV LTR promoter, histidinol
selectable marker; Invitrogen), pREP9 (KpnI, NheI, HindIII, NotI, XhoI, SfiI, and
BamHI cloning site, RSV LTR promoter, G418 selectable marker; Invitrogen),
and pEBVHis (RSV LTR promoter, hygromycin selectable marker, N-terminal
25 peptide purifiable via ProBond resin and cleaved by enterokinase; Invitrogen).
Selectable mammalian expression vectors for use in the invention include
pRc/CMV (HindIII, BstXI, NotI, SbaI, and ApaI cloning site, G418 selection;
Invitrogen), pRc/RSV (HindIII, SpeI, BstXI, NotI, XbaI cloning site, G418
selection; Invitrogen), and others. Vaccinia virus mammalian expression vectors
30 (*see*, Kaufman, *supra*) for use according to the invention include but are not

limited to pSC11 (SmaI cloning site, TK⁻ and β -gal selection), pMJ601 (SalI, SmaI, AflII, NarI, BspMII, BamHI, ApaI, NheI, SacII, KpnI, and HindIII cloning site; TK⁻ and β -gal selection), and pTKgptF1S (EcoRI, PstI, SalI, AccI, HindII, SbaI, BamHI, and HpaI cloning site, TK or XPRT selection).

- Yeast expression systems can also be used according to the invention to express ob polypeptide. For example, the non-fusion pYES2 vector (XbaI, SphI, ShoI, NotI, GstXI, EcoRI, BstXI, BamH1, SacI, KpnI, and HindIII cloning sit; Invitrogen) or the fusion pYESHisA, B, C (XbaI, SphI, ShoI, NotI, BstXI, EcoRI, BamH1, SacI, KpnI, and HindIII cloning site, N-terminal peptide purified with ProBond resin and cleaved with enterokinase; Invitrogen), to mention just two, can be employed according to the invention.

It is further intended that body weight modulator peptide analogs may be prepared from nucleotide sequences derived within the scope of the present invention.

- 15 Analogs, such as fragments, may be produced, for example, by pepsin digestion of weight modulator peptide material. Other analogs, such as muteins, can be produced by standard site-directed mutagenesis of weight modulator peptide coding sequences. Analogs exhibiting "weight modulator activity" such as small molecules, whether functioning as promoters or inhibitors, may be identified by known *in vivo* and/or *in vitro* assays.
- 20 In addition to recombinant expression of ob polypeptide, the present invention envisions and fully enables preparation of ob polypeptide, or fragments thereof, using the well known and highly developed techniques of solid phase peptide synthesis. The invention contemplates using both the popular Boc and Fmoc, as well as other protecting group strategies, for preparing ob polypeptide or
- 25 fragments thereof. Various techniques for refolding and oxidizing the cysteine side chains to form a disulfide bond are also well known in the art.

Derivatives of Ob Peptides

Generally, the present protein (herein the term "protein" is used to include "peptide", unless otherwise indicated) may be derivatized by the attachment of one or more chemical moieties to the protein moiety. The chemically modified derivatives may be further formulated for intraarterial, intraperitoneal, intramuscular subcutaneous, intravenous, oral, nasal, pulmonary, topical or other routes of administration. Chemical modification of biologically active proteins has been found to provide additional advantages under certain circumstances, such as increasing the stability and circulation time of the therapeutic protein and decreasing immunogenicity. See U.S. Patent No. 4,179,337, Davis et al., issued December 18, 1979. For a review, see Abuchowski et al., in *Enzymes as Drugs*. (J.S. Holcberg and J. Roberts, eds. pp. 367-383 (1981)). A review article describing protein modification and fusion proteins is Francis, *Focus on Growth Factors* 3: 4-10 (May 1992) (published by Mediscript, Mountview Court, Friern Barnet Lane, London N20, OLD, UK).

Chemical Moieties For Derivatization

The chemical moieties suitable for derivatization may be selected from among water soluble polymers. The polymer selected should be water soluble so that the protein to which it is attached does not precipitate in an aqueous environment, such as a physiological environment. Preferably, for therapeutic use of the end-product preparation, the polymer will be pharmaceutically acceptable. One skilled in the art will be able to select the desired polymer based on such considerations as whether the polymer/protein conjugate will be used therapeutically, and if so, the desired dosage, circulation time, resistance to proteolysis, and other considerations. For the present proteins and peptides, these may be ascertained using the assays provided herein.

Polymer Molecules

The water soluble polymer may be selected from the group consisting of, for example, polyethylene glycol, copolymers of ethylene glycol/propylene glycol,

The polymer may be of any molecular weight, and may be branched or unbranched. For polyethylene glycol, the preferred molecular weight is between about 2kDa and about 100kDa (the term "about" indicating that in preparations of polyethylene glycol, some molecules will weigh more, some less, than the stated molecular weight) for ease in handling and manufacturing. Other sizes may be used, depending on the desired therapeutic profile (e.g., the duration of sustained release desired, the effects, if any on biological activity, the ease in handling, the degree or lack of antigenicity and other known effects of the polyethylene glycol to a therapeutic protein or analog).

The number of polymer molecules so attached may vary, and one skilled in the art will be able to ascertain the effect on function. One may mono-derivatize, or may provide for a di-, tri-, tetra- or some combination of derivatization, with the same or different chemical moieties (e.g., polymers, such as different weights of polyethylene glycols). The proportion of polymer molecules to protein (or peptide) molecules will vary, as will their concentrations in the reaction mixture. In general, the optimum ratio (in terms of efficiency of reaction in that there is no excess unreacted protein or polymer) will be determined by factors such as the desired degree of derivatization (e.g., mono, di-, tri-, etc.), the molecular weight of the polymer selected, whether the polymer is branched or unbranched, and the reaction conditions.

Attachment of the Chemical Moiety to the Protein

The polyethylene glycol molecules (or other chemical moieties) should be attached to the protein with consideration of effects on functional or antigenic domains of the protein. There are a number of attachment methods available to those skilled in the art. E.g., EP 0 401 384 herein incorporated by reference (coupling PEG to G-CSF), see also Malik et al., Exp. Hematol. 20: 1028-1035 (1992) (reporting pegylation of GM-CSF using tresyl chloride). For example, polyethylene glycol may be covalently bound through amino acid residues via a reactive group, such as, a free amino or carboxyl group. Reactive groups are those to which an activated polyethylene glycol molecule may be bound. The amino acid residues having a free amino group may include lysine residues and the N- terminal amino acid residues; those having a free carboxyl group may include aspartic acid residues glutamic acid residues and the C-terminal amino acid residue. Sulfhydryl groups may also be used as a reactive group for attaching the polyethylene glycol molecule(s). Preferred for therapeutic purposes is attachment at an amino group, such as attachment at the N-terminus or lysine group. Attachment at residues important for receptor binding should be avoided if receptor binding is desired.

N-terminally chemically modified proteins.

One may specifically desire N-terminally chemically modified protein. Using polyethylene glycol as an illustration of the present compositions, one may select from a variety of polyethylene glycol molecules (by molecular weight, branching, etc.), the proportion of polyethylene glycol molecules to protein (or peptide) molecules in the reaction mix, the type of pegylation reaction to be performed, and the method of obtaining the selected N-terminally pegylated protein. The method of obtaining the N-terminally pegylated preparation (i.e., separating this moiety from other monopegylated moieties if necessary) may be by purification of the N-terminally pegylated material from a population of pegylated protein molecules. Selective N-terminal chemically modification may be accomplished by reductive alkylation which exploits differential reactivity of different types of primary amino groups (lysine versus the N-terminal) available for derivatization in

09635864 " 081000

a particular protein. Under the appropriate reaction conditions, substantially selective derivatization of the protein at the N-terminus with a carbonyl group containing polymer is achieved. For example, one may selectively N-terminally pegylate the protein by performing the reaction at pH which allows one to take advantage of the pK_a differences between the ϵ -amino groups of the lysine residues and that of the α -amino group of the N-terminal residue of the protein. By such selective derivatization attachment of a water soluble polymer to a protein is controlled: the conjugation with the polymer takes place predominantly at the N-terminus of the protein and no significant modification of other reactive groups, such as the lysine side chain amino groups, occurs. Using reductive alkylation, the water soluble polymer may be of the type described above, and should have a single reactive aldehyde for coupling to the protein. Polyethylene glycol proprionaldehyde, containing a single reactive aldehyde, may be used.

As mentioned above, a DNA sequence encoding weight modulator peptides as disclosed herein can be prepared synthetically rather than cloned. The DNA sequence can be designed with the appropriate codons for the weight modulator peptide amino acid sequences. In general, one will select preferred codons for the intended host if the sequence will be used for expression. The complete sequence is assembled from overlapping oligonucleotides prepared by standard methods and assembled into a complete coding sequence. See, e.g., Edge, *Nature*, **292**:756 (1981); Nambair et al., *Science*, **223**:1299 (1984); Jay et al., *J. Biol. Chem.*, **259**:6311 (1984).

Synthetic DNA sequences allow convenient construction of genes which will express weight modulator analogs or "muteins". Alternatively, DNA encoding muteins can be made by site-directed mutagenesis of native modulator genes or cDNAs, and muteins can be made directly using conventional polypeptide synthesis.

A general method for site-specific incorporation of unnatural amino acids into proteins is described in Christopher J. Noren, Spencer J. Anthony-Cahill, Michael C. Griffith, Peter G. Schultz, *Science*, **244**:182-188 (April 1989). This method may be used to create analogs of the ob polypeptide with unnatural amino acids.

- 5 The present invention extends to the preparation of antisense nucleotides and ribozymes that may be used to interfere with the expression of the weight modulator proteins at the translational level. This approach utilizes antisense nucleic acid and ribozymes to block translation of a specific mRNA, either by masking that mRNA with an antisense nucleic acid or cleaving it with a ribozyme.
- 10 Antisense nucleic acids are DNA or RNA molecules that are complementary to at least a portion of a specific mRNA molecule (See Weintraub, 1990; Marcus-Sekura, 1988). In the cell, they hybridize to that mRNA, forming a double stranded molecule. The cell does not translate an mRNA in this double-stranded form. Therefore, antisense nucleic acids interfere with the
- 15 expression of mRNA into protein. Oligomers of about fifteen nucleotides and molecules that hybridize to the AUG initiation codon will be particularly efficient, since they are easy to synthesize and are likely to pose fewer problems than larger molecules when introducing them into weight modulator peptide-producing cells. Antisense methods have been used to inhibit the expression of many genes *in vitro*
- 20 (Marcus-Sekura, 1988; Hambor et al., 1988).

- Ribozymes are RNA molecules possessing the ability to specifically cleave other single stranded RNA molecules in a manner somewhat analogous to DNA restriction endonucleases. Ribozymes were discovered from the observation that certain mRNAs have the ability to excise their own introns. By modifying the
- 25 nucleotide sequence of these RNAs, researchers have been able to engineer molecules that recognize specific nucleotide sequences in an RNA molecule and cleave it (Cech, 1988). Because they are sequence-specific, only mRNAs with particular sequences are inactivated.

09635864 081000

Investigators have identified two types of ribozymes, *Tetrahymena*-type and "hammerhead"-type (Hasselhoff and Gerlach, 1988). *Tetrahymena*-type ribozymes recognize four-base sequences, while "hammerhead"-type recognize eleven- to eighteen-base sequences. The longer the recognition sequence, the more likely it is to occur exclusively in the target mRNA species. Therefore, hammerhead-type ribozymes are preferable to *Tetrahymena*-type ribozymes for inactivating a specific mRNA species, and eighteen base recognition sequences are preferable to shorter recognition sequences.

The DNA sequences described herein may thus be used to prepare antisense molecules against and ribozymes that cleave mRNAs for weight modulator proteins and their ligands, thus inhibiting expression of the *ob* gene, and leading to increased weight gain and adiposity.

The present invention also relates to a variety of diagnostic applications, including methods for detecting the presence of conditions and/or stimuli that impact abnormalities in body weight or adiposity, by reference to their ability to elicit the activities which are mediated by the present weight modulators. As mentioned earlier, the weight modulator peptides can be used to produce antibodies to themselves by a variety of known techniques, and such antibodies could then be isolated and utilized as in tests for the presence of particular transcriptional activity in suspect target cells.

Antibody(ies) to the body weight modulators, *i.e.*, the *ob* polypeptide, can be produced and isolated by standard methods including the well known hybridoma techniques. For convenience, the antibody(ies) to the weight modulators will be referred to herein as Ab₁ and antibody(ies) raised in another species as Ab₂.

According to the invention, *ob* polypeptide produced recombinantly or by chemical synthesis, and fragments or other derivatives or analogs thereof, including fusion proteins, may be used as an immunogen to generate antibodies that recognize the

ob polypeptide. Such antibodies include but are not limited to polyclonal, monoclonal, chimeric, single chain, Fab fragments, and an Fab expression library.

Various procedures known in the art may be used for the production of polyclonal antibodies to ob polypeptide a recombinant PTP or derivative or analog thereof.

- 5 For the production of antibody, various host animals can be immunized by injection with the ob polypeptide, or a derivative (*e.g.*, fragment or fusion protein) thereof, including but not limited to rabbits, mice, rats, sheep, goats, etc. In one embodiment, the ob polypeptide or fragment thereof can be conjugated to an immunogenic carrier, *e.g.*, bovine serum albumin (BSA) or keyhole limpet
- 10 hemocyanin (KLH). Various adjuvants may be used to increase the immunological response, depending on the host species, including but not limited to Freund's (complete and incomplete), mineral gels such as aluminum hydroxide, surface active substances such as lysolecithin, pluronic polyols, polyanions, peptides, oil emulsions, keyhole limpet hemocyanins, dinitrophenol, and potentially useful
- 15 human adjuvants such as BCG (*bacille Calmette-Guerin*) and *Corynebacterium parvum*.

For preparation of monoclonal antibodies directed toward the ob polypeptide, or fragment, analog, or derivative thereof, any technique that provides for the production of antibody molecules by continuous cell lines in culture may be used.

- 20 These include but are not limited to the hybridoma technique originally developed by Kohler and Milstein (1975, *Nature* 256:495-497), as well as the trioma technique, the human B-cell hybridoma technique (Kozbor et al., 1983, *Immunology Today* 4:72), and the EBV-hybridoma technique to produce human monoclonal antibodies (Cole et al., 1985, in *Monoclonal Antibodies and Cancer*
- 25 *Therapy*, Alan R. Liss, Inc., pp. 77-96). In an additional embodiment of the invention, monoclonal antibodies can be produced in germ-free animals utilizing recent technology (PCT/US90/02545). According to the invention, human antibodies may be used and can be obtained by using human hybridomas (Cote et al., 1983, *Proc. Natl. Acad. Sci. U.S.A.* 80:2026-2030) or by transforming human

B cells with EBV virus *in vitro* (Cole et al., 1985, in *Monoclonal Antibodies and Cancer Therapy*, Alan R. Liss, pp. 77-96). In fact, according to the invention, techniques developed for the production of "chimeric antibodies" (Morrison et al., 1984, J. Bacteriol. 159:870; Neuberger et al., 1984, Nature 312:604-608; Takeda et al., 1985, Nature 314:452-454) by splicing the genes from a mouse antibody molecule specific for an ob polypeptide together with genes from a human antibody molecule of appropriate biological activity can be used; such antibodies are within the scope of this invention. Such human or humanized chimeric antibodies are preferred for use in therapy of human diseases or disorders (described *infra*), since the human or humanized antibodies are much less likely than xenogenic antibodies to induce an immune response, in particular an allergic response, themselves.

According to the invention, techniques described for the production of single chain antibodies (U.S. Patent 4,946,778) can be adapted to produce ob polypeptide-specific single chain antibodies. An additional embodiment of the invention utilizes the techniques described for the construction of Fab expression libraries (Huse et al., 1989, Science 246:1275-1281) to allow rapid and easy identification of monoclonal Fab fragments with the desired specificity for an ob polypeptide, or its derivatives, or analogs.

Antibody fragments which contain the idiotype of the antibody molecule can be generated by known techniques. For example, such fragments include but are not limited to: the F(ab')₂ fragment which can be produced by pepsin digestion of the antibody molecule; the Fab' fragments which can be generated by reducing the disulfide bridges of the F(ab')₂ fragment, and the Fab fragments which can be generated by treating the antibody molecule with papain and a reducing agent.

In the production of antibodies, screening for the desired antibody can be accomplished by techniques known in the art, *e.g.*, radioimmunoassay, ELISA (enzyme-linked immunosorbent assay), "sandwich" immunoassays,

immunoradiometric assays, gel diffusion precipitin reactions, immunodiffusion assays, *in situ* immunoassays (using colloidal gold, enzyme or radioisotope labels, for example), western blots, precipitation reactions, agglutination assays (*e.g.*, gel agglutination assays, hemagglutination assays), complement fixation assays,

5 immunofluorescence assays, protein A assays, and immunoelectrophoresis assays, etc. In one embodiment, antibody binding is detected by detecting a label on the primary antibody. In another embodiment, the primary antibody is detected by detecting binding of a secondary antibody or reagent to the primary antibody. In a further embodiment, the secondary antibody is labeled. Many means are known in

10 the art for detecting binding in an immunoassay and are within the scope of the present invention. For example, to select antibodies which recognize a specific epitope of an ob polypeptide, one may assay generated hybridomas for a product which binds to an ob polypeptide fragment containing such epitope. For selection of an antibody specific to an ob polypeptide from a particular species of animal,

15 one can select on the basis of positive binding with ob polypeptide expressed by or isolated from cells of that species of animal.

The foregoing antibodies can be used in methods known in the art relating to the localization and activity of the ob polypeptide, *e.g.*, for Western blotting, imaging ob polypeptide *in situ*, measuring levels thereof in appropriate physiological

20 samples, etc.

In a specific embodiment, antibodies that agonize or antagonize the activity of ob polypeptide can be generated. Such antibodies can be tested using the assays described *infra* for identifying ligands.

Immortal, antibody-producing cell lines can also be created by techniques other

25 than fusion, such as direct transformation of B lymphocytes with oncogenic DNA, or transfection with Epstein-Barr virus. See, *e.g.*, M. Schreier et al., "Hybridoma Techniques" (1980); Hammerling et al., "Monoclonal Antibodies And T-cell Hybridomas" (1981); Kennett et al., "Monoclonal Antibodies" (1980); see also

U.S. Patent Nos. 4,341,761; 4,399,121; 4,427,783; 4,444,887; 4,451,570;
4,466,917; 4,472,500; 4,491,632; 4,493,890.

In a specific embodiment, antibodies are developed by immunizing rabbits with synthetic peptides predicted by the protein sequence or with recombinant proteins made using bacterial expression vectors. The choice of synthetic peptides is made after careful analysis of the predicted protein structure, as described above. In particular, peptide sequences between putative cleavage sites are chosen. Synthetic peptides are conjugated to a carrier such as KLH hemocyanin or BSA using carbodiimide and used in Freund's adjuvant to immunize rabbits. In order to prepare recombinant protein, the *gex* vector can be used to express the polypeptide (Smith and Johnson, *supra*). Alternatively, one can use only hydrophilic domains to generate the fusion protein. The expressed protein will be prepared in quantity and used to immunize rabbits in Freund's adjuvant.

The presence of weight modulator in cells can be ascertained by the usual immunological procedures applicable to such determinations. A number of useful procedures are known. Three such procedures which are especially useful utilize either the receptor recognition factor labeled with a detectable label, antibody Ab₁ labeled with a detectable label, or antibody Ab₂ labeled with a detectable label. The procedures may be summarized by the following equations wherein the asterisk indicates that the particle is labeled, and "WM" stands for the weight modulator:

$$A. \text{ WM}^* + \text{Ab}_1 = \text{WM}^*\text{Ab}_1$$

$$B. \text{ WM} + \text{Ab}^* = \text{WM}\text{Ab}_1^*$$

$$C. \text{ WM} + \text{Ab}_1 + \text{Ab}_2^* = \text{Ab}_1\text{WM}\text{Ab}_2^*$$

The procedures and their application are all familiar to those skilled in the art and accordingly may be utilized within the scope of the present invention. The "competitive" procedure, Procedure A, is described in U.S. Patent Nos. 3,654,090 and 3,850,752. Procedure B is representative of the well known competitive assay

In each instance, the weight modulators form complexes with one or more antibody(ies) or binding partners and one member of the complex is labeled with a detectable label. The fact that a complex has formed and, if desired, the amount thereof, can be determined by known methods applicable to the detection of labels.

15 The labels most commonly employed for these studies are radioactive elements, enzymes, chemicals which fluoresce when exposed to ultraviolet light, and others.

A number of fluorescent materials are known and can be utilized as labels. These include, for example, fluorescein, rhodamine and auramine. A particular detecting material is anti-rabbit antibody prepared in goats and conjugated with fluorescein through an isothiocyanate.

The weight modulators or their binding partners can also be labeled with a radioactive element or with an enzyme. The radioactive label can be detected by any of the currently available counting procedures. The preferred isotope may be selected from ^3H , ^{14}C , ^{32}P , ^{35}S , ^{36}Cl , ^{51}Cr , ^{57}Co , ^{58}Co , ^{59}Fe , ^{90}Y , ^{125}I , ^{131}I , and ^{186}Re .

Enzyme labels are likewise useful, and can be detected by any of the presently utilized colorimetric, spectrophotometric, fluorospectrophotometric, amperometric or gasometric techniques. The enzyme is conjugated to the selected particle by reaction with bridging molecules such as carbodiimides, diisocyanates, glutaraldehyde and the like. Many enzymes which can be used in these procedures are known and can be utilized. The preferred are peroxidase, β -glucuronidase, β -D-glucosidase, β -D-galactosidase, urease, glucose oxidase plus peroxidase and alkaline phosphatase. U.S. Patent Nos. 3,654,090; 3,850,752; and 4,016,043 are referred to by way of example for their disclosure of alternate labeling material and methods.

A particular assay system that is to be utilized in accordance with the present invention, is known as a receptor assay. In a receptor assay, the material to be assayed is appropriately labeled and then certain cellular test colonies are inoculated with a quantity of both the labeled and unlabeled material after which binding studies are conducted to determine the extent to which the labeled material binds to the cell receptors. In this way, differences in affinity between materials can be ascertained.

Accordingly, a purified quantity of the weight modulator may be radiolabeled and combined, for example, with antibodies or other inhibitors thereto, after which binding studies would be carried out. Solutions would then be prepared that contain various quantities of labeled and unlabeled uncombined weight modulator, and cell samples would then be inoculated and thereafter incubated. The resulting cell monolayers are then washed, solubilized and then counted in a gamma counter for a length of time sufficient to yield a standard error of $<5\%$. These data are then subjected to Scatchard analysis after which observations and conclusions regarding material activity can be drawn. While the foregoing is exemplary, it illustrates the manner in which a receptor assay may be performed and utilized, in the instance where the cellular binding ability of the assayed material may serve as a distinguishing characteristic. In turn, a receptor assay will be particularly useful

09635864-081000

in the identification of the specific receptors to the present modulators, such as the *db* receptor.

A further assay useful and contemplated in accordance with the present invention is known as a "cis/trans" assay. Briefly, this assay employs two genetic constructs, one of which is typically a plasmid that continually expresses a particular receptor of interest when transfected into an appropriate cell line, and the second of which is a plasmid that expresses a reporter such as luciferase, under the control of a receptor/ligand complex. Thus, for example, if it is desired to evaluate a compound as a ligand for a particular receptor, one of the plasmids would be a construct that results in expression of the receptor in the chosen cell line, while the second plasmid would possess a promoter linked to the luciferase gene in which the response element to the particular receptor is inserted. If the compound under test is an agonist for the receptor, the ligand will complex with the receptor, and the resulting complex will bind the response element and initiate transcription of the luciferase gene. The resulting chemiluminescence is then measured photometrically, and dose response curves are obtained and compared to those of known ligands. The foregoing protocol is described in detail in U.S. Patent No. 4,981,784 and PCT International Publication No. WO 88/03168, for which purpose the artisan is referred.

In a further embodiment of this invention, commercial test kits suitable for use by a medical specialist may be prepared to determine the presence or absence of predetermined transcriptional activity or predetermined transcriptional activity capability in suspected target cells. In accordance with the testing techniques discussed above, one class of such kits will contain at least the labeled weight modulator or its binding partner, for instance an antibody specific thereto, and directions, of course, depending upon the method selected, e.g., "competitive", "sandwich", "DASP" and the like. The kits may also contain peripheral reagents such as buffers, stabilizers, etc.

- 5

10

- 15

- 20

- 25

- (iv) a ligand capable of binding with at least one of the binding partners of at least one of the component(s) to be determined; and

(c) directions for the performance of a protocol for the detection and/or determination of one or more components of an immunochemical reaction between the weight modulator and a specific binding partner thereto.

In accordance with the above, an assay system for screening potential drugs effective to mimic or antagonize the activity of the weight modulator may be prepared. The weight modulator may be introduced into a test system, and the prospective drug may also be introduced into the resulting cell culture, and the culture thereafter examined to observe any changes in the activity of the cells, due either to the addition of the prospective drug alone, or due to the effect of added quantities of the known weight modulator.

As stated earlier, the molecular cloning of the *ob* gene described herein has led to the identification of a class of materials that function on the molecular level to modulate mammalian body weight. The discovery of the modulators of the invention has important implications for the diagnosis and treatment of nutritional disorders including, but not limited to, obesity, weight loss associated with cancer and the treatment of diseases associated with obesity such as hypertension, heart disease and Type II diabetes. In addition, there are potential agricultural uses for the gene product in cases where one might wish to modulate the body weight of domestic animals. Finally, to the extent that one or more of the modulators of the invention are secreted molecules, they can be used biochemically to isolate their receptor using the technology of expression cloning. The discussion that follows with specific reference to the *ob* gene bears general applicability to the class of modulators that a part of the present invention, and is therefore to be accorded such latitude and scope of interpretation.

Therapeutic Implications

In the simplest analysis the *ob* gene determines body weight in mammals, in particular mice and man. The *ob* gene and, correspondingly, cognate molecules, appear to be part of a signaling pathway by which adipose tissue communicates

09635864-031000

with the brain and the other organs. It is believed that the ob polypeptide is itself a signaling molecule, *i.e.*, a hormone. Alternatively ob may be responsible for the generation of a metabolic signal, *e.g.*, a stimulating hormone or an enzyme that catalyzes activation or synthesis of a peptide or steroid hormone. The most important piece of information for distinguishing between these possibilities or considering alternative hypothesis, is the complete DNA sequence of the RNA and its predicted protein sequence. Irrespective of its biochemical function the genetic data suggest that increased activity of *ob* would result in weight loss while decreased activity would be associated with weight gain. The means by which the activity of *ob* can be modified so as to lead to a therapeutic effect depends on its biochemical function.

Administration of recombinant ob polypeptide can result in weight loss. Recombinant protein can be prepared using standard bacterial and/or mammalian expression vectors, all as stated in detail earlier herein. Reduction of ob polypeptide activity (by developing antagonists, inhibitors, or antisense molecules) should result in weight gain as might be desirable for the treatment of the weight loss associated with cancer, AIDS or anorexia nervosa. Modulation of *ob* activity can be useful for reducing body weight (by increasing its activity) or increasing body weight (by decreasing its activity).

The ob polypeptide, or functionally active fragment thereof, or an antagonist thereof, can be administered orally or parenterally, preferably parenterally. Because metabolic homeostasis is a continuous process, controlled release administration of ob polypeptide is preferred. For example, the polypeptide may be administered using intravenous infusion, an implantable osmotic pump, a transdermal patch, liposomes, or other modes of administration. In one embodiment, a pump may be used (see Langer, *supra*; Sefton, *CRC Crit. Ref. Biomed. Eng.* 14:201 (1987); Buchwald et al., *Surgery* 88:507 (1980); Saudek et al., *N. Engl. J. Med.* 321:574 (1989)). In another embodiment, polymeric materials can be used (see *Medical Applications of Controlled Release*, Langer and

Wise (eds.), CRC Pres., Boca Raton, Florida (1974); *Controlled Drug Bioavailability, Drug Product Design and Performance*, Smolen and Ball (eds.), Wiley, New York (1984); Ranger and Peppas, *J. Macromol. Sci. Rev. Macromol. Chem.* 23:61 (1983); see also Levy et al., *Science* 228:190 (1985); During et al., *Ann. Neurol.* 25:351 (1989); Howard et al., *J. Neurosurg.* 71:105 (1989)). In yet another embodiment, a controlled release system can be placed in proximity of the therapeutic target, i.e., the brain, thus requiring only a fraction of the systemic dose (see, e.g., Goodson, in *Medical Applications of Controlled Release*, supra, vol. 2, pp. 115-138 (1984)). Other controlled release systems are discussed in the review by Langer (*Science* 249:1527-1533 (1990)). In another embodiment, the therapeutic compound can be delivered in a vesicle, in particular a liposome (see Langer, *Science* 249:1527-1533 (1990); Treat et al., in *Liposomes in the Therapy of Infectious Disease and Cancer*, Lopez-Berestein and Fidler (eds.), Liss, New York, pp. 353-365 (1989); Lopez-Berestein, *ibid.*, pp. 317-327; see generally *ibid.*)

In a further aspect, recombinant cells that have been transformed with the *ob* gene and that express high levels of the polypeptide can be transplanted in a subject in need of *ob* polypeptide. Preferably autologous cells transformed with *ob* are transplanted to avoid rejection; alternatively, technology is available to shield non-autologous cells that produce soluble factors within a polymer matrix that prevents immune recognition and rejection.

Thus, the *ob* polypeptide can be delivered by intravenous, intraarterial, intraperitoneal, intramuscular, or subcutaneous routes of administration. Alternatively, the *ob* polypeptide, properly formulated, can be administered by nasal or oral administration. A constant supply of *ob* can be ensured by providing a therapeutically effective dose (*i.e.*, a dose effective to induce metabolic changes in a subject) at the necessary intervals, *e.g.*, daily, every 12 hours, etc. These parameters will depend on the severity of the disease condition being treated, other actions, such as diet modification, that are implemented, the weight, age, and sex

of the subject, and other criteria, which can be readily determined according to standard good medical practice by those of skill in the art.

Alternatively, the *ob* gene could be introduced into human fat cells to develop gene therapy for obesity. Such therapy would be expected to decrease body weight. Conversely, introduction of antisense constructs into human fat cells would reduce the levels of active *ob* polypeptide and would be predicted to increase body adiposity.

If *ob* is an enzyme, strategies have begun to be developed for the identification of the substrate and product of the catalyzed reaction that would make use of the recombinant protein. The rationale for this strategy is as follows: If *ob* is an enzyme that catalyzes a particular reaction in adipose tissue, then fat cells from *ob* mice should have high levels of the substrate and very little product. Since it is hypothesized that *db* mice are resistant to the product of this reaction, fat cells from *db* mice should have high levels of the reaction product. Thus, comparisons of lipid and peptide extracts of *ob* and *db* adipose tissue using gas chromatography or other chromatographic methods should allow the identification of the product and substrate of the key chemical reaction. The prediction would be that the recombinant *ob* protein would catalyze this reaction. The product of this reaction would then be a candidate for a signaling molecule that modulates body weight.

As noted above, the functional activity of the *ob* polypeptide can be effected transgenically,, *e.g.*, by gene therapy. In this respect, a transgenic mouse model can be used. The *ob* gene can be used in complementation studies employing transgenic mice. Transgenic vectors, including viral vectors, or cosmid clones (or phage clones) corresponding to the wild type locus of candidate gene, can be constructed using the isolated *ob* gene. Cosmids may be introduced into transgenic mice using published procedures (Jaenisch, *Science* **240**, 1468-1474, 1988). The constructs are introduced into fertilized eggs derived from an intercross between F1 progeny of a C57BL/6J *ob/ob* X DBA intercross. These

09635864-081000

Genotype at the *ob* loci in cosmid transgenic animals can be determined by typing animals with tightly linked RFLPs or microsatellites which flank the mutation and

15 Alternatively, *ob* genes can be tested by examining their phenotypic effects when
express in antisense orientation in wild-type animals. In this approach, expression
of the wild type allele is suppressed, which leads to a mutant phenotype.

The antisense transgene will be placed under control of its own promoter or another promoter expressed in the correct cell type, and placed upstream of the SV40 poly A site. This transgene will be used to make transgenic mice.

Transgenic mice will also be mated ovarian transplants to test whether *ob*
30 heterozygotes are more sensitive to the effects of the antisense construct.

In the long term, the elucidation of the biochemical function of the *ob* gene product (the ob polypeptide or protein) is useful for identifying small molecule agonists and antagonists that affect its activity.

000780 4985E960

Pharmaceutical Compositions

In yet another aspect of the present invention, provided are pharmaceutical compositions of the above. Such pharmaceutical compositions may be for administration for injection, or for oral, pulmonary, nasal or other forms of administration. In general, comprehended by the invention are pharmaceutical compositions comprising effective amounts of protein or derivative products of the invention together with pharmaceutically acceptable diluents, preservatives, solubilizers, emulsifiers, adjuvants and/or carriers. Such compositions include diluents of various buffer content (e.g., Tris-HCl, acetate, phosphate), pH and ionic strength; additives such as detergents and solubilizing agents (e.g., Tween 80, Polysorbate 80), anti-oxidants (e.g., ascorbic acid, sodium metabisulfite), preservatives (e.g., Thimersol, benzyl alcohol) and bulking substances (e.g., lactose, mannitol); incorporation of the material into particulate preparations of polymeric compounds such as polylactic acid, polyglycolic acid, etc. or into liposomes. Hylauronic acid may also be used. Such compositions may influence the physical state, stability, rate of in vivo release, and rate of in vivo clearance of the present proteins and derivatives. See, e.g., Remington's Pharmaceutical Sciences, 18th Ed. (1990, Mack Publishing Co., Easton, PA 18042) pages 1435-1712 which are herein incorporated by reference. The compositions may be prepared in liquid form, or may be in dried powder, such as lyophilized form.

Oral Delivery

Contemplated for use herein are oral solid dosage forms, which are described generally in Remington's Pharmaceutical Sciences, 18th Ed. 1990 (Mack Publishing Co. Easton PA 18042) at Chapter 89, which is herein incorporated by reference. Solid dosage forms include tablets, capsules, pills, troches or lozenges, cachets or pellets. Also, liposomal or proteinoid encapsulation may be used to formulate the present compositions (as, for example, proteinoid microspheres reported in U.S. Patent No. 4,925,673). Liposomal encapsulation may be used and the liposomes may be derivatized with various polymers (E.g., U.S. Patent No. 5,013,556). A description of possible solid dosage forms for the therapeutic

is given by Marshall, K. In: *Modern Pharmaceutics* Edited by G.S. Banker and C.T. Rhodes Chapter 10, 1979, herein incorporated by reference. In general, the formulation will include the protein (or chemically modified protein), and inert ingredients which allow for protection against the stomach environment, and
5 release of the biologically active material in the intestine.

Also specifically contemplated are oral dosage forms of the above derivatized proteins. Protein may be chemically modified so that oral delivery of the derivative is efficacious. Generally, the chemical modification contemplated is the attachment of at least one moiety to the protein (or peptide) molecule itself, where
10 said moiety permits (a) inhibition of proteolysis; and (b) uptake into the blood stream from the stomach or intestine. Also desired is the increase in overall stability of the protein and increase in circulation time in the body. Examples of such moieties include: Polyethylene glycol, copolymers of ethylene glycol and propylene glycol, carboxymethyl cellulose, dextran, polyvinyl alcohol, polyvinyl
15 pyrrolidone and polyproline. Abuchowski and Davis, Soluble Polymer-Enzyme Adducts. In: "Enzymes as Drugs", Hocenberg and Roberts, eds., Wiley-Interscience, New York, NY, (1981), pp 367-383; Newmark, et al., J. Appl. Biochem. 4: 185-189 (1982). Other polymers that could be used are poly-1,3-dioxolane and poly-1,3,6-tioxocane. Preferred for pharmaceutical usage, as
20 indicated above, are polyethylene glycol moieties.

For the protein (or derivative) the location of release may be the stomach, the small intestine (the duodenum, the jejunum, or the ileum), or the large intestine. One skilled in the art has available formulations which will not dissolve in the stomach, yet will release the material in the duodenum or elsewhere in the
25 intestine. Preferably, the release will avoid the deleterious effects of the stomach environment, either by protection of the protein (or derivative) or by release of the biologically active material beyond the stomach environment, such as in the intestine.

To ensure full gastric resistance a coating impermeable to at least pH 5.0 is essential. Examples of the more common inert ingredients that are used as enteric coatings are cellulose acetate trimellitate (CAT), hydroxypropylmethylcellulose phthalate (HPMCP), HPMCP 50, HPMCP 55, polyvinyl acetate phthalate (PVAP), Eudragit L30D, Aquateric, cellulose acetate phthalate (CAP), Eudragit L, Eudragit S, and Shellac. These coatings may be used as mixed films.

A coating or mixture of coatings can also be used on tablets, which are not intended for protection against the stomach. This can include sugar coatings, or coatings which make the tablet easier to swallow. Capsules may consist of a hard shell (such as gelatin) for delivery of dry therapeutic i.e. powder; for liquid forms, a soft gelatin shell may be used. The shell material of cachets could be thick starch or other edible paper. For pills, lozenges, molded tablets or tablet triturates, moist massing techniques can be used.

The therapeutic can be included in the formulation as fine multiparticulates in the form of granules or pellets of particle size about 1mm. The formulation of the material for capsule administration could also be as a powder, lightly compressed plugs or even as tablets. The therapeutic could be prepared by compression.

Colorants and flavoring agents may all be included. For example, the protein (or derivative) may be formulated (such as by liposome or microsphere encapsulation) and then further contained within an edible product, such as a refrigerated beverage containing colorants and flavoring agents.

One may dilute or increase the volume of the therapeutic with an inert material. These diluents could include carbohydrates, especially mannitol, α -lactose, anhydrous lactose, cellulose, sucrose, modified dextrans and starch. Certain inorganic salts may be also be used as fillers including calcium triphosphate, magnesium carbonate and sodium chloride. Some commercially available diluents are Fast-Flo, Emdex, STA-Rx 1500, Emcompress and Avicell.

To aid dissolution of the therapeutic into the aqueous environment a surfactant might be added as a wetting agent. Surfactants may include anionic detergents such as sodium lauryl sulfate, dioctyl sodium sulfosuccinate and dioctyl sodium sulfonate. Cationic detergents might be used and could include benzalkonium chloride or benzethonium chloride. The list of potential nonionic detergents that could be included in the formulation as surfactants are lauromacrogol 400, polyoxyl 40 stearate, polyoxyethylene hydrogenated castor oil 10, 50 and 60, glycerol monostearate, polysorbate 40, 60, 65 and 80, sucrose fatty acid ester, methyl cellulose and carboxymethyl cellulose. These surfactants could be present in the formulation of the protein or derivative either alone or as a mixture in different ratios.

Additives which potentially enhance uptake of the protein (or derivative) are for instance the fatty acids oleic acid, linoleic acid and linolenic acid.

Controlled release formulation may be desirable. The drug could be incorporated into an inert matrix which permits release by either diffusion or leaching mechanisms i.e. gums. Slowly degenerating matrices may also be incorporated into the formulation. Another form of a controlled release of this therapeutic is by a method based on the Oros therapeutic system (Alza Corp.), i.e. the drug is enclosed in a semipermeable membrane which allows water to enter and push drug out through a single small opening due to osmotic effects. Some entric coatings also have a delayed release effect.

Other coatings may be used for the formulation. These include a variety of sugars which could be applied in a coating pan. The therapeutic agent could also be given in a film coated tablet and the materials used in this instance are divided into 2 groups. The first are the nonenteric materials and include methyl cellulose, ethyl cellulose, hydroxyethyl cellulose, methylhydroxy-ethyl cellulose, hydroxypropyl cellulose, hydroxypropyl-methyl cellulose, sodium carboxy-methyl

000000-49852360

5

Pulmonary Delivery

10
15
20
25

Some specific examples of commercially available devices suitable for the practice of this invention are the Ultravent nebulizer, manufactured by Mallinckrodt, Inc., St. Louis, Missouri; the Acorn II nebulizer, manufactured by Marquest Medical Products, Englewood, Colorado; the Ventolin metered dose inhaler, manufactured

All such devices require the use of formulations suitable for the dispensing of protein (or derivative). Typically, each formulation is specific to the type of device employed and may involve the use of an appropriate propellant material, in addition to the usual diluents, adjuvants and/or carriers useful in therapy. Also, the use of liposomes, microcapsules or microspheres, inclusion complexes, or other types of carriers is contemplated. Chemically modified protein may also be prepared in different formulations depending on the type of chemical modification or the type of device employed.

Formulations suitable for use with a nebulizer, either jet or ultrasonic, will typically comprise protein (or derivative) dissolved in water at a concentration of about 0.1 to 25 mg of biologically active protein per mL of solution. The formulation may also include a buffer and a simple sugar (e.g., for protein stabilization and regulation of osmotic pressure). The nebulizer formulation may also contain a surfactant, to reduce or prevent surface induced aggregation of the protein caused by atomization of the solution in forming the aerosol.

Formulations for use with a metered-dose inhaler device will generally comprise a finely divided powder containing the protein (or derivative) suspended in a propellant with the aid of a surfactant. The propellant may be any conventional material employed for this purpose, such as a chlorofluorocarbon, a hydrochlorofluorocarbon, a hydrofluorocarbon, or a hydrocarbon, including trichlorofluoromethane, dichlorodifluoromethane, dichlorotetrafluoroethanol, and 1,1,1,2-tetrafluoroethane, or combinations thereof. Suitable surfactants include sorbitan trioleate and soya lecithin. Oleic acid may also be useful as a surfactant.

Formulations for dispensing from a powder inhaler device will comprise a finely divided dry powder containing protein (or derivative) and may also include a

bulking agent, such as lactose, sorbitol, sucrose, or mannitol in amounts which facilitate dispersal of the powder from the device, e.g., 50 to 90% by weight of the formulation. The protein (or derivative) should most advantageously be prepared in particulate form with an average particle size of less than 10 μm (or 5 microns), most preferably 0.5 to 5 μm , for most effective delivery to the distal lung.

Nasal Delivery

Nasal delivery of the protein (or derivative) is also contemplated. Nasal delivery allows the passage of the protein to the blood stream directly after administering the therapeutic product to the nose, without the necessity for deposition of the product in the lung. Formulations for nasal delivery include those with dextran or cyclodextran.

Methods of Treatment, Methods of Preparing a Medicament

In yet another aspect of the present invention, methods of treatment and manufacture of a medicament are provided. Conditions alleviated or modulated by the administration of the present derivatives are those indicated above.

Dosages

For all of the above molecules, as further studies are conducted, information will emerge regarding appropriate dosage levels for treatment of various conditions in various patients, and the ordinary skilled worker, considering the therapeutic context, age and general health of the recipient, will be able to ascertain proper dosing. Generally, for injection or infusion, dosage will be between 0.01 μg of biologically active protein/kg body weight, (calculating the mass of the protein alone, without chemical modification), and 100 $\mu\text{g}/\text{kg}$ (based on the same). The dosing schedule may vary, depending on the circulation half-life of the protein or derivative used, and the formulation used.

Administration with other compounds

For therapy associated with obesity, one may administer the present protein (or derivatives) in conjunction with one or more pharmaceutical compositions used for treating other clinical complications of obesity, such as those used for treatment of diabetes (e.g., insulin), high blood pressure, high cholesterol, and other adverse conditions incident to obesity. Also, other appetite suppressants may be co-administered, e.g., amphetamines. Administration may be simultaneous (for example, administration of a mixture of the present protein and insulin) or may be in serriatim.

Diagnostic Implications

10 The human cDNA clones that have recently been isolated have been sequenced as presented herein. This facilitates the determination of the complete sequence of the human gene (see Figure 20). DNA sequences from the introns of the human *ob* gene have been obtained (Figure 20), and these have been used to prepare PCR primers to PCR amplify the coding sequence of the *ob* gene from human genomic
15 DNA so as to identify mutations or allelic variants of the *ob* gene, all in accordance with protocols described in detail earlier herein. Specific PCR primers for amplifying human genomic *ob* are described in a specific Example, *infra*.

The current hypothesis is that heterozygous mutations in the *ob* gene will be associated with mild/moderate obesity while homozygous mutations would be associated with severe obesity. If this is true, it would allow the ascertainment of people at risk for the development of obesity and make possible the application of drug treatment and/or lifestyle changes before an increased body weight is fully developed.

Alternatively, the presence of microsatellites that segregate with mutant forms of
25 human *ob* can be used for diagnosis. Various PCR primers, including those based
on the nucleotide sequence provided in Figure 20A, can be used in this respect.

5

10

Agricultural Applications

15

20

25

Alternatively, the introduction of the cloned genes into transgenic domestic animals would allow one to potentially decrease body weight and adiposity by

Conversely, increases in body fat might be desirable in other circumstances such as for the development of Kobe beef or fatty liver to make foie gras. This could be accomplished by targeting an antisense *ob* transgene to fat, or by using gene knockout technology. Alternatively, where an increase in body weight at percentage of fat is desired, an inhibitor or antagonist of the *ob* polypeptide can be administered. Such inhibitors or antagonists include, but are not limited to, antibodies reactive with the polypeptide, and fragments of the polypeptide that bind but do not activate the *ob* receptor, *i.e.*, antagonists of *ob* polypeptide.

Development of small molecule agonists and antagonists of the *ob* factor will be greatly facilitated by the isolation of its receptor. This can be accomplished by preparing active *ob* polypeptide and using it to screen an expression library using standard methodology. Receptor binding in the expression library can be tested by administering recombinant polypeptide prepared using either bacterial or mammalian expression vectors, and observing the effects of short term and continuous administration of the recombinant polypeptide on the cells of the expression library, or by directly detecting binding of *ob* polypeptide to the cells.

As it is presently believed that the *ob* receptor is likely to be located in the hypothalamus and perhaps liver, preferably cDNA libraries from these tissues will be constructed in standard expression cloning vectors. These cDNA clones would next be introduced into COS cells as pools and the resulting transformants would be screened with active ligand to identify COS cells expressing the *ob* receptor.

Positive clones can then be isolated so as to recover the cloned receptor. The cloned receptor would be used in conjunction with the *ob* ligand (assuming it is a hormone) to develop the necessary components for screening of small molecule modulators of *ob*.

5 enough material is provided for nuclear magnetic resonance (NMR), infrared (IR), Raman, and ultraviolet (UV), especially circular-dichroism (CD), spectroscopic analysis. In particular NMR provides very powerful structural analysis of molecules in solution, which more closely approximates their native environment (Marion et al., 1983, Biochem. Biophys. Res. Comm. 113:967-974; Bar et al., 10 1985, J. Magn. Reson. 65:355-360; Kimura et al., 1980, Proc. Natl. Acad. Sci. U.S.A. 77:1681-1685). Other methods of structural analysis can also be employed. These include but are not limited to X-ray crystallography (Engstrom, A., 1974, Biochem. Exp. Biol. 11:7-13).

15 Analysis of co-crystals provides detailed information about binding, which in turn
allows for rational design of ligand agonists and antagonists. Computer modeling
can also be used, especially in connection with NMR or X-ray methods
(Fletterick, R. and Zoller, M. (eds.), 1986, Computer Graphics and Molecular
Modeling, in *Current Communications in Molecular Biology*, Cold Spring Harbor
20 Laboratory, Cold Spring Harbor, New York).

25 According, in addition to rational design of agonists and antagonists based on the structure of ob polypeptide, the present invention contemplates an alternative method for identifying specific ligands of ob receptor using various screening assays known in the art.

- 249:404-406), very large libraries can be constructed (10^6 - 10^8 chemical entities). A second approach uses primarily chemical methods, of which the Geysen method (Geysen et al., 1986, *Molecular Immunology* 23:709-715; Geysen et al. 1987, *J. Immunologic Method* 102:259-274) and the recent method of Fodor et al. (1991, *Science* 251, 767-773) are examples. Furka et al. (1988, 14th International Congress of Biochemistry, Volume 5, Abstract FR:013; Furka, 1991, *Int. J. Peptide Protein Res.* 37:487-493), Houghton (U.S. Patent No. 4,631,211, issued December 1986) and Rutter et al. (U.S. Patent No. 5,010,175, issued April 23, 1991) describe methods to produce a mixture of peptides that can be tested as agonists or antagonists.

- 25 In another aspect, synthetic libraries (Needels et al., 1993, "Generation and screening of an oligonucleotide encoded synthetic peptide library," Proc. Natl. Acad. Sci. USA 90:10700-4; Lam et al., International Patent Publication No. WO 92/00252, each of which is incorporated herein by reference in its entirety), and

the like can be used to screen for *ob* receptor ligands according to the present invention. With such libraries, receptor antagonists can be detected using cell that express the receptor without actually cloning the *ob* receptor (Lam et al., *supra*).

- Alternatively, assays for binding of soluble ligand to cells that express
- 5 recombinant forms of the *ob* receptor ligand binding domain can be performed. The soluble ligands can be provided readily as recombinant or synthetic *ob* polypeptide.

- The screening can be performed with recombinant cells that express the *ob* receptor, or alternatively, using purified receptor protein, *e.g.*, produced
- 10 recombinantly, as described above. For example, the ability of labeled, soluble or solubilized *ob* receptor that includes the ligand-binding portion of the molecule, to bind ligand can be used to screen libraries, as described in the foregoing references.

EXAMPLE SECTION

- 15 The following outlines the method used to identify the genetic material that is exemplary of the present invention. This endeavor comprises four sequential steps: A) Genetic Mapping, B) Physical Mapping, C) Candidate Gene Isolation, and D) Mutation detection. Following confirmation that the murine gene in object was isolated (Step D), the homologous human gene was sought, and both the
- 20 murine and human genes and putative proteins were characterized. The steps are summarized in greater detail, below.

A. Genetic Mapping

- The *ob* mutation was segregated in genetic crosses and standard linkage analysis was used to position the mutation relative to RFLPs (restriction fragment length
- 25 polymorphisms). These data placed the *ob* gene in an ~ 5cM interval on proximal mouse chromosome 6. (5cM is a measurement of genetic distance

000780" 49855960

The genetic resolution of the experiments described above was inadequate to clone *ob*, principally because none of the genetic markers were in tight linkage. In order to identify the requisite tightly linked RFLPs, additional probes were isolated and the genetic cross was expanded. A method known as chromosome microdissection was used to isolate random pieces of DNA from proximal mouse chromosome 6 (Bahary et al., *Mammalian Genome* 4: 511-515, 1993). Individual cloned probes were tested for tight linkage to *ob*. On the basis of these studies one probe, D6Rck13, also termed psd3, was selected for further analysis owing to its genetic proximity to *ob*.

This probe was used to genotype 835 *ob* progeny from interspecific and intersubspecific crosses, which indicated that D6Rck13 is nonrecombinant in all 835 animals as reported in Bahary et al. In the course of physical mapping, a new polymorphic marker was identified from a cosmid subclone derived from YAC 53A6. This new marker was positioned between D6Rck13 and the *ob* gene and was used to genotype the additional 771 informative meioses from intraspecific intercross and backcross. A single animal #167 was identified to bear a recombination crossover between *ob* and D6Rck39. These studies indicated that D6Rck39/D6Rck13 is ~ 0.06 cM from *ob*. An additional probe, Pax-4, was identified that was .12 cM proximal to *ob*. Pax-4 was recombinant in two animals; #111 and 420. Pax-4 is a pseudogene that was previously mapped to proximal mouse chromosome 6 by Gruss and co-workers (Gruss et al. *Genomics* 11:424-434, 1991). On this basis, it was determined that the *ob* gene resides in

the ~ 0.2cM interval between Pax-4 and D6Rck13. This led to efforts to clone the interposing DNA in an effort to isolate *ob*.

B. Physical Mapping

The cloning of the DNA in this interval made use of yeast artificial chromosomes (YACs), a relatively new cloning vector that allows the cloning of long stretches of contiguous DNA often more than 1 million base pairs in length.

Firstly, yeast artificial chromosomes were isolated using D6Rck13 and Pax-4. This was accomplished by preparing purified DNA probes and using them to isolate the corresponding YACs. These YACs (#8, 16, 107 and 24) were isolated and initially characterized, and on the basis of the resulting analyses it was concluded that YAC 16 was the YAC that extended furthest distally, *i.e.*, closest to *ob*. The key end of YAC #16 was then recovered, and it was determined that this end was closer to *ob* than Pax-4. This end was termed 16M(+). This conclusion was reached because it was shown that this probe was not recombinant in animal #420 (as was Pax-4). This end was sequenced and used to develop a PCR assay. This PCR assay was used to screen a YAC library. Four positive clones were isolated. Subsequent characterization of these YACs by end-rescuing, restriction mapping, pulse field gel electrophoresis, and Southern blots with the genetic crosses determined that two of these YACs, *adu* and *aad*, were critical for subsequent studies. YAC *aad* is a 550 kB nonchimeric YAC which extended furthest distally. Therefore, the distal end of this YAC, *aad*(pICL) was used to complete the physical map. YAC *adu* is 370 kB nonchimeric YAC and its distal end, *adu*(+), was determined to be nonrecombinant in all the *ob* progeny of the genetic crosses including animals #111 and 167, suggesting that the *ob* gene might reside in this YAC.

A PCR assay for these two ends, *aad*(pICL) and *adu*(+) was developed and used for isolating more YACs and P1 clones to continue physical mapping. The important P1 clones isolated by this effort included 498, 499, 500 (isolated using a

probe derived from *aad*(pICL)) and 322, 323 and 324 (using a probe from *adu*(+)).

In the meantime, YACs isolated by D6Rck13 (53A6, 25A8, 25A9, 25A10) were characterized. These studies determined that 53A6 extended furthest proximally toward the *aad* YAC. The size of the gap between 53A6 and *aad* was determined ~70 kB. The key end of 53A6, 53(pICL) was then used to screen three available YAC libraries and a P1 library. A critical P1 clone, 325, was isolated. This P1 clone overlapped with the P1 clones isolated by *aad*(pICL) as described above, and therefore served to close the gap between 53(pICL) and *aad*(pICL). As a result, the whole contig, containing YACs and P1 clones, of ~2.5 million base pairs in length, and which spanned Pax4, 16M(+), *adu*(+), *aad*(pICL), 53(pICL), D6Rck39 and D6Rck13, was cloned. By carefully mapping the sites of recombination apparent in animal #111 and 167, it was concluded that *ob* was situated in a 400 kB interval. To provide a working DNA source for isolating the *ob* gene, about 500 kB covering this nonrecombination region was isolated in a total of 24 P1 clones. These P1 clones, including 322 and 323, which later were proved to be useful clones, were used for exon trapping.

The physical map of the portion of the chromosome carrying *ob* is shown in Figure 7A. Figure 7B represents the YAC contig. Figure 7C represents the P1 contig.

C. Isolation of Candidate Genes

The method used to isolate genes in this interval was exon trapping. This method used a commercial vector to identify exon DNA (*i.e.*, coding sequences) by selecting for functional splice acceptor and donor sequences in genomic DNA introduced into a test construct. The DNA from these P1s were grown and subcloned into the exon trapping vector. These clones were short inserts cloned into a Bluescript vector. Each clone was PCR amplified with PCR primers corresponding to plasmid sequences that flanked the insert. The PCR

5

10

25

Thus, clones were identified both by their size and the fact that hybridization of DNA probes corresponding to this artifact hybridized to the corresponding bands on a Southern blot of the gel. In this way, 185 out of 192 clones were excluded from further evaluation. Exclusion of the artifacts on the basis of size alone was not possible, as this could have, in the end, led to exclusion of the exon corresponding to *ob*.

Thus, of the 192 exons, a total of seven exons were selected for further study. Templates for sequencing the seven exons were prepared, and sequencing was performed. The sequences for the 7 exons were analyzed and it was found that 4 were identical and one was an apparent artifact. In particular, clone 1D12 contained the "HIV sequence," *i.e.*, the artifact band. This left three exons for further analysis: 1F1, 2G7 and 1H3. 1F1 was eliminated because it mapped outside the critical region. PCR primers for both 1H3 and 2G7 were selected and synthesized.

The sequence of the exon on 2G7 was determined, and is shown in Figure 10 (SEQ ID NO:7). PCR primers for 2G7 were selected and synthesized. The portions of the sequence corresponding to the PCR primers are underlined. The primers used were:

5' CCA GGG CAG GAA AAT GTG (T_m = 60.0) (SEQ ID NO:8)
 3' CAT CCT GGA CTT TCT GGA TAG G (T_m = 60.0) (SEQ ID NO:9)

These primers amplified genome DNA with PCR conditions as follows: 25-30 cycles at 55° annealing x 2', 72° extension x 2', 94° denaturation x 1' in standard PCR buffer. These primers were also used to generate a labeled probe by including ³²P dCTP in the PCR reaction with a corresponding reduction in the amount of cold dCTP.

A RT PCR was performed on a variety of tissue RNAs and it was concluded that 2G7 was expressed exclusively in white fat among the tissues examined (Figure 11A). Thereafter, ^{32}P -labelled 2G7 was hybridized to a Northern blot of tissue RNAs (Figure 11B) and showed that its RNA was expressed at high level in fat tissue but was either not expressed or expressed at very low levels in all other tissues (where the signals may be the result of fat contaminating the tissue preparations). Ten μg of total RNA from each of the tissues listed was electrophoresed on an agarose gel with formaldehyde. The probe was hybridized at 65° in a standard hybridization buffer, Rapid Hype (Amersham). The size of the RNA was approximately 4.9 kB. At this point 2G7 was considered to be a viable candidate gene for *ob* and was analyzed further.

D. Mutation Detection

In order to confirm that 2G7 encoded the *ob* gene, it was necessary to demonstrate differences in the levels of RNA expression of DNA sequence of this gene in mutant as compared to wild type animals. Two separate mutations of the *ob* gene are available for study, C57BL/6J *ob/ob* (1J) and Ckc/Smj *ob/ob* (2J). These will be referred hereinafter as 1J and 2J, respectively. (Informal nomenclature is used to refer to the mouse strains studied. Throughout this specification and in the drawings, it will be understood that C57BL/6J refers to C57BL/6J +/+; CKC/smj refers to SM/Ckc-^{Dac}-+/+; CKC/smj *ob/ob* refers to SM/Ckc-^{Dac}-*ob*^{2J}/*ob*^{2J}). RNA was prepared from fat tissue that had been isolated from 1J, 2J, and control animals. Total RNA for each sample was treated with DNase and then reverse transcribed using oligo-dT as a primer and reverse transcriptase. The resulting single stranded cDNA was then PCR amplified either with the 2G7 primers (conditions shown above) for the lower band or commercially available actin primers for the upper band. The RT PCR products were run on a 1% agarose TBE gel that was stained with ethidium bromide (Figure 12A). Using RT-PCT it was found that while 2G7 mRNA was expressed in 1J and all the other control mice, it was completely missing in 2J mouse. No signal was detected after 30

Since 2J mutation is relatively recent and is maintained as a coisogenic strain, this result was the first available evidence that indicated that 2G7 is an exon from the *ob* gene. The mutation is likely located in the promoter region which leads to total abortion of the mRNA synthesis. The presence of signal in 1J mouse in this RT-PCT experiment suggested that 1J might carry a point mutation which does not result in a gross change in size of the RNA sample. In addition, 2G7 mRNA was absent, when tested by RT PCR, from four additional 2J animals.

10 This result was confirmed on a Northern blot (Figure 12B). Fat cell RNA was prepared from each of the strains (C57Bl/6J, 1J, CKC/smj, and 2J). Ten μ g of these RNAs were run out. The blot was probed with the 2G7 probe that was PCR labeled, by amplification of the material, i.e., band, in Figure 11 using 32 P-dCTP in the PCR reaction. Actin is a control for the amount of RNA loaded. The actin
15 signal is fairly similar in all of the samples. The *ob* signal is absent in brain because the mRNA is specific to fat cells.

The results of the Northern analysis confirm that 2G7 RNA was absent in 2J mice. The *ob* RNA is absent in the CKC/smj *ob/ob* mice because in this obese mutant strain the gene is disrupted such that no RNA is made. In addition, the level of 2G7 RNA was increased ~10-20 fold in 1J as well as *db/db* fat. These results are compatible with the hypothesis that *ob* either encodes circulating hormone or is responsible for the generation of a signal from fat cells that modulates body weight. These results supported the conclusion that 2G7 is the *ob* gene and predicted that 1J mice have a point mutation, probably a nonsense mutation leading to a premature translation termination.

These Northern results have been replicated using fat cell RNA preparations from four different 2J animals (Figure 13). In this assay, *ap2* is a fat-specific transcript

that was used as a control much the same as actin in Figure 12B. There is no significance to the varying density of the ap2 band. ap2 was labeled by designing PCR primers from the published ap2 sequence. The RT PCR products of fat cell RNA were then relabeled using the same protocol for PCR labeling. This analysis demonstrates the presence of *ob* mRNA in normal homozygous or heterozygous animals, and its absence from 2J mutant animals.

The mutation has been identified in 1J mice. The mutation is a C to T base change that results in change of an arginine to an apparent premature stop codon at amino acid 108, and in all likelihood accounts for the 1J mutation (Figure 14) despite high level expression of the *ob* mRNA (see Figure 12 and 13, C57BL/6J *ob/ob* lanes).

More recently, Southern blots have been used to conclude that the 2J mutation is the result of a detectable DNA change at the 5' end of *ob* that appears to completely abolish RNA expression. The exact nature of this possible rearrangement remains to be determined.

A genomic Southern blot of DNA from the CKC/smj (SM/Ckc-+^{Dac}) and C57BL/6J mice using four different restriction endonucleases was performed in order to determine whether the mutant *ob* yielded a unique fragment pattern (Figure 15A). Approximately 10 μ g of DNA (derived from genomic DNA prepared from liver, kidney, or spleen) was restriction digested with the restriction enzyme indicated. The DNA was then electrophoresed in a 1% agarose TBE gel. The DNA was transferred to an imobilon membrane and hybridized to the PCR labeled 2G7 probe. The key band is the uppermost band in the BglII digest for the CKC/smj *ob/ob* (SM/Ckc-+^{DAC} *ob*^{2J}/*ob*^{2J}) DNA. This band is of higher molecular weight than in the other strain, indicating a mutation in this strain.

Figure 15B is a southern blot of a BglII digest of genomic DNA from the progeny of an *ob*^{2J}/+ x *ob*^{2J}/+ cross. Some of the DNAs have only the upper band, some

cDNA Cloning and Sequence Determination of *ob*

- 5 Using the labeled 2G7 PCR probe, a total of 50 mouse cDNA clones from a murine fat cell λ gt11 cDNA library (Clontech 5'-STRETCH cDNA from testicular fat pads of Swiss mice, #ML3005b), and thirty cross hybridizing human cDNA clones from a human fat cell λ gt10 cDNA library (Clontech 5'-STRETCH cDNA from abdomen #HL1108a) were isolated. Library screening was performed
10 using the plaque lift procedure. The filters from the plaque lift were denatured using the autoclave method. The filters were hybridized in duplicate with the PCR labeled 2G7 probe (Rapid Hybe buffer, 65°C, overnight). After a 2-4 hour prehybridization, the filters were washed in 2x SSC, 2% SDS, twice for 30 minutes at 65°C and exposed to SRY Llim. Duplicate positives were plaque
15 purified. Plaque purified phage were PCR amplified using commercially available vector primers, *e.g.*, λ gt10 and λ gt11. The resulting PCR products corresponded to the cDNA insert for each phage with a small amount of vector sequence at either end. The bands were gel purified and sequenced using the ABI automated sequencer and the vector primers to probe the DNA polymerase.
- 20 The raw sequencing data were then manually examined base by base to correct mishearing from the computer program. As the correct sequence became available, the downstream primers were synthesized and used to continue sequencing. Such experiments were repeated until each available cDNA clone was sequenced and synthesized into a contig. To date, ~3000 base pairs from the 5' end of the mRNA has been compiled. One of the cDNA clones extended to the 5'
25 end of the mRNA since its sequence was identical to that of the 5' RACE product of fat tissue RNA (data not shown).

The sequence data revealed that there is a 167 amino acid open reading frame (Figure 1). A Kozak translation initiation consensus sequence was present with an adenosine residue three bases upstream of the ATG. Two classes of cDNA were found differing by inclusion or exclusion of a single glutamine codon. This residue is found in a position immediately 3' to the splice acceptor of the 2G7 exon. Since the CAG codon of glutamine includes a possible AG splice acceptor sequence, it appears that there is slippage at the splice acceptor site with an apparent 3 base pairs deletion in a subset of the cDNA, as shown below.

```

      gln  ser  val
10      ag CAG TCG GTA  (with glutamine)      (SEQ ID NO:16)
      ↑
      (splice acceptor site)

      ser  val
15      ag CAG TCG GTA  (without glutamine)     (SEQ ID NO:17)
      ↑
      (splice acceptor site)

```

The "ag" in the sequences above corresponds to the assumed intron sequence upstream of the glutamine codon, and AG is the putative alternative splice site. This glutamine residue is located in a highly conserved region of the molecule and its importance for biological activity is as yet unknown.

A putative N-terminal signal sequence was detected, the signal cleavage site of which is predicted to be carboxy terminal to the alanine residue at amino acid position 21. This putative signal sequence was confirmed by application of a computer algorithm to the method of von Heijne (*Nucl. Acids Res.* **14**, 4683, 1986). Using this technique, the most probable signal sequence was identified in the polypeptide coding region corresponding to amino acids 1-23, having the sequence:

MCWRPLCRFLWLWSYLSYVQA ↑ VP (SEQ ID NO:10)

in which the arrow indicates the putative signal sequence cleavage site. The rest of the amino acid sequence was largely hydrophilic and did not have any notable

structural motifs or membrane spanning domains other than the N-terminal signal sequence. Specifically, we did not find consensus sequences for N-linked glycosylation or dibase amino acid sequences indicative of protein cleavage in the predicted processed protein (Sabatini and Adesnik, *The metabolic basis of inherited disease*, C.V. Scriver et al. eds., McGraw-Hill: New York, pp. 177-223). Data base search using Blast and Block programs did not identify any homologous sequence.

Human fat tissue RNA was analyzed on Northern blot, RNA species of similar size to the mouse *ob* gene was detected. Sequencing and analysis of cDNA clones revealed that human *ob* also encodes 167 amino acid polypeptide (Figures 2 and 3). Two classes of cDNA with or without three base pairs deletion were found in human as well (Figure 6). The mouse and human *ob* genes were highly homologous in the predicted coding region, but had only 30% homology in the available 3' and 5' untranslated regions. An N-terminal signal sequence was also present in the human *ob* polypeptide. Comparison of the human and mouse *ob* polypeptide sequences showed that the two molecules share an overall 84% identity at amino acid level (Figure 4). The N-termini of the mature proteins from both species share even higher homology, with only four conservative and three nonconservative amino acid substitutions among the N-terminal 100 amino acid residues.

Genomic DNA was isolated from mouse, rat, rabbit, vole, cat, cow, sheep, pig, human, chicken, eel, and drosophila, and restriction digested with EcoR1. The digests were electrophoresed on 1% agarose TBE gel. DNA was transferred to an imobilon membrane and probed with the PCR labeled 2G7 probe. The filter was hybridized at 65°C and washed with 2x SSC, 0.2% SDS at 65°C twice for twenty minutes each wash, *i.e.*, there were two buffer changes. These data indicate that *ob* is conserved among vertebrates (Figure 16). Note in this regard that there is a 2+ signal in eel DNA; eel is a fish.

EXAMPLE: Expression of *ob* In Bacteria

10

15

Mnde-5' (murine five prime primer):

CTTATGTTCA TATGGTGCCG ATCCAGAAAG TC (SEQ ID NO:12)

20 Mnde-3' (murine three prime primer):

TCCCTCTACA TATGTCTTGG GAGCCTGGTG GC (SEQ ID NO:13)

Hnde-5' (human five prime primer):

TCTATGTCCA TATGGTGCCG ATCCAAAAG TC (SEQ ID NO:14)

Hnde-3' (human three prime primer):

25 TTCCTTCCCA TATGGTACTC CTTGCAGGAA GA (SEQ ID NO:15)

The primers contain a 6-base pair mismatch in the middle that introduces NdeI restriction sites at each end of the PCR fragment. Phage carrying either the mouse or human cDNA were PCR amplified using those primers. The PCR

product was digested with NdeI and gel purified on a 1% low melting point agarose gel. The gel purified bands were subcloned into the pET vector. The resulting plasmids were sequenced to ensure that mutations were not introduced during the PCR amplification step of cloning. Constructs for the human and murine cDNA that encodes and that lacks glutamine 49 have been prepared. In particular, pET 15b constructs containing either the human or the mouse *ob* coding sequence, minus signal sequence and fused to a Hig-Tag, have been made using a PCR cloning method. The constructs have been sequenced to ensure no sequence errors were introduced into the coding region of the *ob* gene during the PCR amplification step.

Two resultant plasmid constructs, pETM9 and pETH14, were selected to transform a bacterial expression host. Upon induction with 1 mM IPTG under optimal conditions, the transformed bacteria were able to produce 100-300 μ g/ml of the *ob* fusion. The majority of the *ob* fusion protein was found in the inclusion body. After solubilization with 6M guanidine-HCl or urea, the fusion protein was purified through a His-binding (Ni-chelation) resin column. The conditions for column purification of the *ob* fusion protein (including binding, washing, and eluting) were established experimentally. The *ob* fusion protein binds to the resin at 5 mM imidazol/6M guanidine-HCl and stays bound at up to 20 mM imidazol/6M guanidine-HCl. The protein can be eluted from the resin at 60 mM imidazol/6M guanidine (Figure 18A,B). Both the purified human and mouse *ob* fusion proteins were further dialyzed in PBS to remove guanidine-HCl from the preparation and used to raise polyclonal antibodies.

In order to test the biological activity of the fusion protein products, the refolding conditions for the purified protein was tested and developed. This involves initial dialysis of the fusion protein in 1 M guanidine solution, followed by dilution with 0.4 M arginine solution. The His-Tag was removed from the fusion proteins before biological function assay. The tag removal was achieved by treating the fusion protein with thrombin from human placenta.

5 space may only need a simple gel filtration to be purified from other host proteins and will not be denatured during such process.

These peptides were conjugated to KLH, and the peptide-KLH conjugates were used to immunize rabbits using standard techniques. Polyclonal antisera specific for each peptide is recovered from the rabbits.

EXAMPLE: *In Vitro* Translocation of an ob Polypeptide

25 In order to confirm the presence of a functional signal sequence, a human cDNA that included the entire open reading frame was subcloned into the pGEM vector.

Only the human cDNA was used in this experiment because suitable mouse subclones were not recovered. Positive strand human *ob* RNA was transcribed using sp6 polymerase and used in an *in vitro* translation reaction with and without canine pancreatic microsomal membranes. The primary translation product

5 migrated with an apparent molecular weight of ~18 kD, which is consistent with that predicted by the cDNA sequence. Inclusion of the microsomal membranes in the reaction inhibited the overall efficiency of translation ~5 fold. Nevertheless, approximately 50-70% of the *ob* primary translation product was truncated by

10 the signal sequence is functional (Figure 19A). The size of the primary translation product of interleukin-1 α RNA, which does not encode a signal sequence, was unchanged when microsomal membranes were included in the reaction. In order to confirm that translocation of the *ob* protein had taken place, the *in vitro* translation products were treated with Proteinase-K. Protease treatment resulted in

15 the complete proteolysis of the 18 kD primary translation product while the 16 kD processed form was unaffected by the enzyme treatment, indicating that it had translocated into the lumen of the microsomes (Figure 19B). These data are compatible with the hypothesis that *ob* is a secreted molecule.

After signal sequence cleavage, two cysteine residues would remain within the

20 predicted protein raising the possibility that the molecule contains a disulfide bond characteristic of other secreted polypeptides (Shen and Rutter, 1984, Science 224:168-171).

EXAMPLE: Characterization of the *ob* Gene

To establish the relationship between obesity and genetic alterations in the *ob* gene

25 in humans, the sequence of the human *ob* gene was determined (Figure 20A) (SEQ ID NO:). Specific primers from the human coding sequence were used to screen a human P1 library. Three different P1 clones were obtained, grown up, and PCR amplified using primers flanking the splicing site between the first and second

The gene structure of both the murine and human genes was characterized using PCR assays and other standard techniques. The mouse *ob* gene was found to

25 polymerase may be employed to yield more easily readable sequences for mutation
detection.

EXAMPLE: Expression of *ob* in Yeast

Following the positional cloning of *ob*, it became important to uncover the physiological mechanism by which the *ob* protein reduces food intake and body weight. The first step in this direction was to recombinantly produce a functional protein using an expression system. In addition to the successful bacterial expression system, a yeast expression system was also selected. Yeast expression has several attractive features for expressing *ob*. The most important is that biologically active eukaryotic proteins are more likely to be produced. The *ob* polypeptide is secreted by mammalian cells. Protein secretion is very similar for all eukaryotes, which means that the yeast secretory apparatus is much more similar to the mammalian secretory pathway than bacterial secretory pathways would be. In particular, protein modifications of *ob* seen in mammalian cells would likely also be seen in the expression through the yeast secretory system. In addition, protein folding is carried out in passage through the secretory apparatus and thus delivering *ob* through the yeast secretory apparatus is likely to give a properly folded protein with native biological activity. This is significant for *ob* because the two cysteine residues may form a disulfide bridge. In contrast to secretory pathways, the reducing environment of the cell cytoplasm prevents formation of disulfide bridges, and therefore it is essential that *ob* pass through the secretory pathway in order for this disulfide bond to form *in vivo*. Other advantages have to do with the ease and quickness of manipulating yeast, the availability of vectors and strains, and the vast experience in yeast recombinant technology.

A *Pichia pastoris* expression system was chosen for four reasons: (1) it has higher levels of heterologous protein expression than other yeast systems such as *S. cerevisiae*; (2) protein glycosylation is more similar to the mammalian system in *P. pastoris* than *S. cerevisiae* (although glycosylation sites were not detected in *ob* using a computer search, there still remained the possibility of glycosylation at unrecognized sites); (3) *P. pastoris* secretes very few proteins natively, and thus it

The vector chosen was pPIC.9. This vector contains a cloning site just

10 The cloning strategy was the following: PCR amplify *ob* cDNA using a 5' primer that contained at its 3' end sequence complementary to the sequence of *ob* just following the predicted leader peptide cleavage site, and at its most 5' end a sequence complementary to the 3' end of the alpha-mating factor sequence of the vector. The 5' primer also contains an XhoI site. The 3' primer was designed to
15 have at its 3' end a sequence complementary to the last few amino acids of *ob* and an EcoRI site at its 5' end. Following PCR amplification, the PCR product was digested with XhoI and EcoRI and cloned into similarly digested pPIC.9.

For the two mouse *ob* constructs, transformed yeast clones were screened for protein expression. As evidence that the transformed yeast contain *ob*, a DNA dot-blot assay and a colony hybridization assay were done which both showed *ob* sequence within the transformed yeast but not within the untransformed yeast. Furthermore, the transformed yeast now secreted a 16 kDa protein into the culture media whereas the untransformed yeast does not secrete a protein of this size

(Figure 23A). This is the predicted size of *ob*. Individual clones for both mouse constructs have been identified that are high expressors for *ob*, and currently a purification strategy is being developed to purify *ob* to homogeneity. One strategy has been to purify *ob* on a cation exchange column (Figure 23B); preliminary data suggest that a strong cation exchanger may be useful. However, after cation exchange chromatography, the putative *ob* product is lost. This indicates the presence of a protease in the sample.

One strategy to overcome this problem is to prepare *ob*-His tag fusions for expression in yeast (Figure 22). Further evaluation has demonstrated that *ob* without a His tag associates tightly with a Ni-chelation column. Purification of the *ob* polypeptide by Ni-chelation, followed by gel filtration, yielded a product of sufficient purity for mass spectral analysis. Mass spec confirms the molecular weight of the expressed protein is identical to the expected molecular weight, which strongly confirms that *ob* has been successfully expressed in *Pichia*.

However, the Ni-chelation/gel filtration purification protocol does not yield a *ob* polypeptide in sufficiently pure form. Additional small molecules are present. It does appear that the proteolytic activity elutes from the Ni-chelation column in the void volume. Accordingly, a three step purification process is planned: Ni-chelation, followed by cation exchange (which eliminates the small molecule contaminants), followed by gel filtration.

Estimating expression level by Coomassie blue staining of SDS-PAGE gels reveals approximately 10 mg/L when yeast are grown in shaker flasks. These levels are expected to increase in fermentation vessels, and we are about to initiate fermentation with the hopes of obtaining larger quantities of protein. Regarding the human *ob* constructs, transformed yeast clones containing high copy numbers of the *ob* gene have been identified, and these are expected to express *ob* protein. As antibodies are developed, these will be used to confirm the identity of the secreted 16 kDa protein.

The gene product of the mouse *ob* locus plays an important role in regulating body weight. We establish that the *ob* protein circulates in mouse, rat and human plasma. The circulating form in all three species has an identical molecular weight by SDS-PAGE to the deduced polypeptide sequence without the signal sequence, suggesting that *in vivo* the protein is not processed after cleavage of the signal sequence. The *ob* protein is absent in plasma from C57/Bl6J *ob/ob* mice and is present at ten-fold higher concentrations in plasma of *db/db* mice and twenty-fold higher levels in plasma of *fa/fa* rats relative to controls. These obese animal mutants have been suggested to be resistant to its effects. There were seven fold differences in plasma levels of the *ob* protein within a group of six lean human subjects. Daily injections of the recombinant mouse *ob* protein dramatically reduce body mass in *ob/ob* mice, have significant effects on body weight of wild type mice but have no effect on *db/db* mice. These data show that the gene product of the *ob* locus serves an endocrine function to regulate body weight. We propose that the protein encoded by the *ob* gene be named Leptin derived from the Greek root *leptós* meaning thin.

Materials and Methods

Rabbits were immunized with recombinant protein in Freund's adjuvant. (HRP, Inc) Immunopurified anti-mouse *ob* antibodies were prepared by passage of antiserum over a sepharose 4B column conjugated to the recombinant protein as described [Harlow, 1988 #444]. Immunoprecipitation of mouse plasma was carried out as follows. 0.5 ml of plasma from mouse, rat and human containing approximately 2.5 mM EDTA was pre-cleared with unconjugated sepharose-4B at room temperature with rocking for 2 hours. The sepharose was removed by spinning and 50 μ l added of a 50% slurry of antibody-conjugated sepharose containing affinity purified antibody at a concentration of 1 mg/ml of packed sepharose. 0.5 ml of 2x RIPA buffer was added to give final binding conditions as follows: 50 mM Tris-HCl, pH7.5, 100 mM NaCl, 1% NP-40, 0.1% SDS, 0.5% sodium deoxycholate and 0.025% sodium azide. The reaction was carried out overnight at 4°C with rocking. The antibody-conjugated sepharose was washed 8 times with RIPA buffer and rinsed three times with PBS and run on 15% SDS-PAGE. The proteins were

transferred to nitrocellulose and Western blotted with a biotinylated immunopurified antibody against the recombinant protein. The secondary used was HRP-streptavidin and ECL was used for detection.

To quantitate the amount of *ob* in mouse serum, increasing amounts of the refolded recombinant mouse *ob* protein (0.01, 0.1, 0.5, 2.0, 15.0 ng) was added to 100 μ l of C57BL/6J *ob/ob* plasma and incubated at 4°C for 3 hours with the protein A sepharose conjugated antibody. After extensive washing with buffer A (10 mM Na Phosphate buffer, pH 7.4; 100 mM NaCl; 1% Triton X-100, 5 mM EDTA, 1 mM PMSF) samples were resuspended in sample buffer and loaded on a 15% SDS-PAGE and transferred to a nitrocellulose membrane. Western blotting was performed using an immunopurified biotinylated anti-amino terminus antibody as a primary antibody and HRP-Streptavidin as a secondary antibody followed by ECL detection.

Cytoplasmic extracts were prepared by homogenizing adipose tissue in NDS buffer by polytron and dounce homogenization and removal of nuclei by centrifuging at 700 g. [10 mM Tris, pH 7.5, 10 mM NaCl, 60 mM ICCI, 0.15 mM spermine, 0.5 mM spermidine, 14 mM β -Mercaptoethanol, 0.5 mM EGTA, 2 mM EDTA, 0.5% NP-40]

Immunoprecipitations were performed as above except that immunopurified anti-human *ob* antibodies were used. For the ELISA, 100 μ l of a 1 μ g/ml solution of immunopurified anti-human *ob* antibody was dissolved in a borate buffered PBS solution and applied overnight to microtiter (Corning cat. #2595) plates at 4°C. The plates were then washed 4 times with borate saline solution containing 0.05% Tween 20 and excess liquid was removed. Plates were blocked by incubation at RT for 2 hours with 240 μ l per well of borate saline buffer containing 0.3% gelatin and then washed and dried. Either known amounts of a refolded human *ob* protein or plasma samples in 100 μ l volume were incubated in individual wells overnight at 4°C. After washing, the plates were incubated with 100 μ l of a biotinylated immunopurified anti-human antibody (0.1 mg/ml in a gelatine borate buffered solution) for 4 hours at room temperature. After washing Horse Radish Peroxidase-Streptavidin was added to the plates (0.1 μ g/ml in borate buffer, 0.3% gelatin). HRP substrate solution (ABTS, 0.3 mg/ml and H₂O₂, 0.01% in citric acid) was then used for detection and the OD at 414 nm was read to quantitate the antibody binding.

The mouse and human *ob* coding sequence were PCR amplified from plasmids containing *ob* cDNA sequences and subcloned into the pPIC.9 plasmid (Invitrogen). The human 5' primer was: 5' GTATCTCTCGAGAAAAGAGTGCCCATCCAAAAAGTCCAAG 3' and the 3' primer was 5' GCGCGAATTCTCAGCACCCAGGGCTGAGGTC 3'. For mouse the 5' primer was: 5' GTATCTCTCGAGAAAAGAGTGCCTATCCAGAAAGTCCAGG 3' and the 3' primer was 5' GCGCGAATTCTCAGCATTTCAGGGCTAACATC 3'. The 5' primer for both mouse and human

000180-1985960

contains an XhoI site at the 5' end and coding sequences for the last 4 aa of the alpha-mating factor signal sequence present in the vector pPIC.9. This vector directs secretion of heterologously expressed genes from the cell into the culture media. The 5' PCR primer also includes the first 19 n.t.'s of the *ob* open reading frame after the signal sequence cleavage site before the alanine at amino acid position 21. The 3' primer contains an EcoRI site at its 5' end which is immediately followed by sequences complementary to the putative *ob* stop codon. The PCR conditions were as follows: denaturing for 1' at 94, annealing for 1' at 55 and extension for 2.5' at 72. Low-cycle PCR (15 cycles) and the proof-reading polymerase PFU (Stratagene) were used to limit the number of PCR-generated mutations. The PCR products were digested with XhoI and EcoRI and cloned into similarly digested vector pPIC.9. All constructs were sequenced on both strands to ensure the absence of any PCR-generated mutations. Clones were transformed into *Pichia pastoris* (His-) by the spheroplast method and selected on histidine deficient media. Approximately 200 clones of mouse and human were screened for high-copy number integration by a colony hybridization assay and the high copy number clones were then assayed for *ob* expression initially by coomassie staining showing the presence of a novel 16 kd protein present in the culture media of transformed yeast. The 16 kd band was confirmed to be *ob* using antibodies raised against the bacterially expressed protein. The recombinant proteins were purified by a two-step purification method described below. Mass spectrometry and cyanogen bromide treatment were performed as described [Beavis, 1990 #804].

The entire *ob* coding sequence of the mouse and human *ob* genes C-terminal to the signal sequence were subcloned into the Pet15b expression vector (Novagen) and overexpressed in *Escherichia coli* [BL21(DE3)pLYsS] using the T7 RNA polymerase system [Studier, 1990 #803]. Cells grown at 30°C to an absorbency of 0.7 at 595 nM and induced with 0.5 mM isopropyl-β-D-thiogalacto-pyranoside overnight were collected by low-speed centrifugation. Lysis was performed by three cycles of freeze thaw and DNA digestion was done with DNaseI. Membrane extraction was performed by sonication and detergent solubilization, and the final inclusion body pellet was dissolved in 6M guanidine-HCl, 20mM HEPES, pH8.4. Recombinant *ob* proteins were purified under denaturing conditions by IMAC using a Ni-ion affinity column and washing with increasing amounts of imidazole. Purified denatured *ob* protein was then stored in 6 M guanidine-HCl, 10 mM sodium acetate (NaAc), pH5, and reduced using 1 mM DTT at room temperature for 1 hour. Denaturation was performed by diluting the reduced protein into 20% glycerol, 5 mM CaCl₂, 5 mM NaAc, pH5, through mixing and incubation at room temperature for 8-12 hours. After denaturation the pH was adjusted to 8.4 by addition of Tris to 10 mM, and the hexahistidine tag was removed by thrombin cleavage. Cleaved, renatured protein was repurified by IMAC to separate product from thrombin and uncleaved fusion protein.

Cleaved, renatured protein elutes from the Ni-ion affinity column at 40 mM imidazole, whereas thrombin is not retained and uncleaved fusion protein elutes at 0.2 mM imidazole. Product was then concentrated, treated with 100 mM EDTA and 10 mM potassium ferricyanide and further purified by gel filtration using Pharmacia superdex 75 16/60 column.

An Ellman's assay was conducted as described [Ellman, 1959 #798]. Ellman's reagent was prepared by dissolving 39.6 mg 5,5'-dithio-bis(2-nitrobenzoic acid) (DTNB) in 10 ml 0.05 M phosphate, pH 8. A calibration curve was constructed in the concentration range of 10-120 mM free sulfhydryl (using a 1 mM stock solution of reduced DTT) at 412 nm. Each assay was performed using 0.02 ml Ellman's reagent and a total reaction mixture of 0.5 ml. The measured extinction coefficient was $12974 \text{ M}^{-1}\text{cm}^{-1}$ for free sulfhydryl group (correlation coefficient 0.99987), which is within 5 % of the previously reported value of $13600 \text{ M}^{-1}\text{cm}^{-1}$.

50 μl of 2 $\mu\text{g/ml}$ pure gel filtered protein, corresponding to a possible free sulfhydryl concentration of about 24 μM in the final reaction mixture, was subjected to Ellman's assay. The resulting solution gave A_{412} of about 0.02, suggesting that two cysteine residues in the protein are in oxidized state to form cystine or that their free sulfhydryl groups are completely buried within the inaccessible core of the folded protein. Identical results were obtained by conducting the same assay on unfolded protein in the presence of 6 M guanidine-HCl.

Mice were individually caged in a pathogen-free environment and acclimated to a diet containing 35% (w/w) Laboratory Rodent Diet 5001 (PMP Feeds, Inc.), 5.9% (w/w) tapioca pudding mix (General Foods) and 59.1% water which has an energy content of 1.30 kcal/gm. The diet was sterilized by autoclave and packed into 60 mm plastic dishes which were fixed to the tops of 100 mm petri dishes. Tapioca gives the diet a pasty texture making it difficult for the animal to spread the food in the cage. The 100 mm lid recovers the small amount of food spilled by the animal. A fresh dish of food was placed into the cage each morning and the previous day's dish was removed and weighed. The difference in weight provided a measure of daily food consumption. Effects of recombinant protein on food intake and body weight were measured in three strains of mice: C57Bl/6J ob/ob, C57 Bl/Ks db/db and CBA/J +/+, purchased from the Jackson Laboratory. Thirty mice from each strain were divided into groups of 10. One group from each strain received daily intraperitoneal (i.p.) injections of the refolded bacterial ob protein at a dose of 5 $\mu\text{g/g/day}$ in 300 μl of PBS. A second group received i.p. injections of the same volume of PBS. These control mice received injections of the PBS dialysate of the recombinant protein. The PBS was cleared of endotoxin using an Acticlean ETOX column. A third group of animals did not receive injections. Food intake was recorded daily and body weight measurements were recorded regularly over a 3.5 week interval. For the pair feeding experiment, the food intake of a separate group of ob mice was matched on a daily basis to that consumed by the ob mice receiving protein.

The ob Protein Circulates in Mouse, Rat and Human Plasma

The *ob* protein from mouse plasma migrates with an apparent molecular weight of 16 kD by SDS-PAGE. The electrophoretic mobility is identical to the recombinant *ob* protein secreted by yeast after signal sequence removal. (Fig. 24A) The protein was not detected in plasma from C57BL/6J *ob/ob* mice that have a nonsense mutation at codon 105. Several different antisera failed to identify the truncated 105 residue polypeptide chain predicted by the cDNA sequence.

A ten-fold increase in the level of circulating protein was observed in *db/db* mice relative to a control animal (Fig. 24A). Immunoprecipitation of plasma from wild type and *fa/fa* rats revealed a twenty-fold increase in the level of the *ob* protein in the mutant rat compared to wild type. (Fig. 24B) The *db* mutation results in an obese phenotype identical to that seen in *ob* mice [Bahary, 1990 #31]. fatty rats are obese as a result of a recessive mutation in a gene homologous to *db* [Truett, 1991 #409]. In order to quantitate the level of *ob* in mouse plasma, increasing amounts of recombinant protein were added to *ob* serum and immunoprecipitated. (Fig. 24C) A linear increase of the signal intensity on Western blots was seen with increasing amounts of recombinant protein. Comparison of the signal intensity of the native protein in mouse plasma to the standards indicated that the circulating level of the *ob* protein in wild type mice is ~20 ng/ml. These data demonstrate that the immunoprecipitations and Western blots were performed under conditions of

The purified human protein expressed in *Pichia* had a molecular mass of 16,024±3 Da as determined by mass spectrometry [Beavis, 1990 #804]. This value is in agreement with the mass calculated from the amino acid sequence of the protein containing a single intramolecular disulfide bridge (16,024 Da). Matrix-assisted laser desorption mass spectrometric analysis of cyanogen bromide cleavage products of the protein indicates that cysteines 117 and 167 are linked through an intramolecular disulphide bond. (Fig. 26B) Cyanogen bromide cleaves carboxyterminal to methionine residues.

Mouse ob protein was expressed in *E. coli* from a PET 15b plasmid as an insoluble fusion protein, with a twenty residue, N-terminal hexahistidine tag containing a thrombin cleavage site. Bacterial inclusion bodies were solubilized using guanidine-HCl and purified under denaturing conditions using immobilized metal ion affinity chromatography (IMAC). (Fig. 27) Purified, denatured fusion protein was reduced, diluted and permitted to refold in aqueous solution at room temperature. Following thrombin cleavage, renatured mouse ob protein containing four additional N-terminal residues (Gly-Ser-His-Met) was repurified by IMAC to >98% homogeneity, as judged by SDS-PAGE and mass spectrometry. Matrix-assisted laser desorption mass spectrometry gave a measured mass of $16,414 \pm 3$ Da (predicted mass = 16,415 Da). Both reducing and non-reducing SDS-PAGE gels demonstrated a single molecular species with apparent and molecular weight of 16 kD (data not shown).

Dynamic light scattering using a DP801 Molecular Size Detector (Protein Solutions, Inc.) demonstrated that the renatured mouse ob protein was largely monomeric, with some higher-order aggregates. The protein was treated with

In wild type mice there was a small but significant decrease in body weight following administration of the recombinant *ob* protein. (Fig. 29A, Table 1). After five days of protein injection, the treated mice lost an average of .5 grams while control mice gained .4 grams ($p < .02$). At two subsequent time points the animals receiving protein weighed significantly less than the mice receiving daily injections of PBS. The significance of the weight change was reduced at the later time points. In the animals that lost weight, the food intake was not significantly different from control animals. The injections of PBS had a small but significant effect on food intake and body weight in *ob*, *db* and wild type mice as compared to mice not receiving injections ($p < .05$).

The effects of protein vs PBS injections on body weight are tabulated for C57Bl/6J ob/ob, C57Bl/Ks db/db and wild type mice. Shown are the average values, standard errors and statistical significance at each of the time points listed. Four animals in the CBA/J and ob groups and all of the db mice were sacrificed after two weeks of injections. Statistical significance was determined using a two sample of test.

114

An endocrine function for the protein product of the *ob* locus was first suggested by Coleman, who showed that the body weight of *ob/ob* mice was reduced after parabiotic union to normal or *db* mice [Coleman, 1978 #42]. Our results support this hypothesis by showing that *ob* protein circulates in the bloodstream and that injections of recombinant protein reduce body weight. The molecular weight of the gene product encoded by the *ob* gene is ~16 kD, which is equal to the 146 amino acid sequence carboxy terminal to the signal sequence. The recombinant *ob* protein is not modified when expressed in *Pichia pastoris*. Expression of mammalian genes in *Pichia* generally results in the formation of the correct protein structure [Cregg, 1993 #792]. These findings suggest that the *ob* protein is not glycosylated and is not post-translationally processed *in vivo*. The data do not exclude the possibility that the *ob* protein is noncovalently bound to itself or other proteins in plasma or adipose tissue. Although proteolytic cleavage of the protein has not been excluded, lower molecular weight forms of the *ob* protein were not detected by any of the antisera used, including four anti-peptide antibodies.

The *ob* protein has two cysteine residues and circulates as a monomer in human, and as a monomer and dimer in mouse. An intramolecular disulphide bond typical of secreted molecules is found when the human protein is expressed in *Pichia pastoris* suggesting that it is likely to be present *in vivo*. This is supported by the bioactivity of the recombinant bacterial protein, which has an intramolecular disulphide bond. The mouse *ob* protein can be found in plasma as a monomer and as a dimer. That monomer and dimer are seen when the mouse *ob* protein is expressed in yeast shows that the propensity of the mouse protein to form a dimer is a result of differences in the primary sequence relative to human. While it is clear that the monomer has bioactivity, the functional activity of the dimer is unknown.

The effect of the *ob* protein on food intake and body weight in *ob* mice is dramatic. After three weeks treatment, the *ob* mice receiving daily injections of recombinant protein had lost 40% of their weight and were consuming 40 % as much food as control animals. Moreover, the weight of the treated *ob* mice had not yet equilibrated at the time the experiment was terminated. The results of the pair feeding experiment indicate weight loss is a result of effects on both food intake and energy expenditure. Thus, a separate group of *ob* mice whose caloric intake was restricted to that of *ob* mice receiving protein lost significantly

less weight than the animals receiving protein. The reduction in food intake in *ob/ob* mice to a level lower than that of wild type mice, within a day of receiving the *ob* protein, indicates that they are especially sensitive to its effects. Indeed, the *ob* receptor may be upregulated in these animals. Food intake of treated *ob* mice became relatively constant after five days of treatment. If this is the result of the protein having reached steady state levels, it would suggest that the protein has a relatively long half life [Goodman, 1990 #793]. This conclusion is consistent with data from parabiosis experiments [Coleman, 1978 #42; Weigle, 1988 #349].

Effects of recombinant protein on the body weight of wild type mice were small but statistically significant during the first two weeks of the study. While the difference in weight between wild type mice receiving protein vs. PBS was sustained at later time points, the statistical significance of the data had greatly diminished after three weeks. The early weight loss could not be accounted for by a difference in food intake. Presumably, the measurement of food intake was not precise enough to detect a decrease resulting in a one gram difference in body weight during treatment. These observations differ from the results of previous experiments in which wild type rodents have been joined by parabiotic union to *db* mice, *fatty* rats, rats with hypothalamic lesions and rats rendered obese by a high calorie diet [Coleman, 1978 #42; Harris, 1987 #800; Harris, 1989 #799; Hervey, 1959 #305]. In each case, the wild type animals become anorectic and lose copious amounts of weight. As the levels of *ob* protein are increased in *db* mice and *fa* rats and the level of *ob* RNA is increased in mice with hypothalamic lesions, it is likely that wild type mice can respond to *ob* when it circulates in plasma at a sufficiently high level. The findings reported here are consistent with the possibility that the levels of the administered protein were below endogenous levels, leading to equilibration at a slightly lower body weight. Quantitation of the circulating levels of the *ob* protein in the treated mice will resolve this issue. Immunoprecipitations have suggested that the levels of circulating *ob* protein were not substantially elevated in the wild type mice receiving protein.

The lesser effect of the protein on wild type mice and the absence of a response in *db* mice makes it unlikely that the treatment has nonspecific or aversive effects. All of the *db* mice lost a small amount of weight during the treatment period, whether or not they were receiving the *ob* protein. The *db* animals were markedly hyperglycemic and the weight loss is likely to be the result of diabetes and not the experimental protocol. C57BL/Ks *db/db* mice often develop diabetes and begin to lose small amounts of weight when of the age of

00635864 081000

The failure to detect the truncated 105 amino acid protein predicted by the cDNA sequence of the *ob* gene in C57Bl/6J *ob/ob* mice suggests that the mutant protein is either degraded or not translated. However, the possibility that the antisera used do not detect this truncated protein cannot be excluded. The observed ten-fold increase in the levels of the *ob* protein in *db* mice compared to wild type suggests that the *ob* protein is overproduced when there is resistance to its effects. These data correlate with studies of the *ob* mRNA (*Next Example*). As mentioned, previous experiments have shown that mutations of the mouse *db* and the rat *fa* genes, which map to homologous chromosomal regions, result in overproduction of a plasma factor that suppresses body weight [Truett, 1991 #409; Coleman, 1978 #42; Hervey, 1959 #305]. In both cases, it has been suggested that the mutant animals are resistant to the effects of the *ob* protein. This possibility is confirmed by the observation that the *ob* protein has no effect on body weight or food intake when administered to *db* mice.

The site of action of the *ob* protein is unknown. The protein affects both food intake and energy expenditure, a finding consistent with clinical studies indicating that alterations of both systems act to regulate body weight [Leibel, 1995 #795; Keesey, 1984 #796]. The hypothalamus is likely to be downstream of *ob* in the pathway that controls body weight, although direct effects on a variety of organs are possible.

concentrations of ethanol from 10% to 100%, each for 5 min. at 4°C. Further incubation of tissues with xylene (1h) and paraffin (2h) were performed at 65°C. Embedded wt and db/db fat tissues were sectioned and mounted on to the same conditions later. Sections were baked at 65°C for 1h and treated with xylene and serial dilutions of ethanol from 100% to 50%, each for 3 min. at room temperature. Antisense RNA probe of ob gene was synthesized by in vitro transcription of linearized ob gene coding sequence upstream of a Sp6 RNA polymerase promoter. In situ hybridization was carried out exactly according to Schaeren-Wiemers and Gerfin-Moser[7].

RNA Preparation and Cell Culture

Total RNA and Northern blots were prepared as described[3].

Stromal vascular cells and adipocytes were prepared according to Rodbell and RNA from both fractions was prepared according to Dani et al[8, 9]. After sub-cloning, 3T3-F442 cells were grown in Dulbecco's modified Eagle medium containing 10% foetal bovine serum (defined as standard medium) [10]. At confluence, cells were treated in standard medium supplemented with 2 nM triiodothyronine (T3) and 17 nM insulin. Twelve days later, RNA was prepared as above.

Gold ThioGlucose Treatment

Two month old female CBA/J mice were treated with a single intraperitoneal injection of aurothioglucose (Sigma A0632) at a dose of .2 mg/g in normal saline. Control animals were injected with normal saline. Mice were weighed one month after the treatment. Adipose tissue RNA was isolated from those treated animals whose weight had increased more than twenty grams post GTG treatment.

RESULTS

The *ob* gene was recently found to be expressed in adipose tissue[3]. As adipose tissue is composed of many cell types including adipocytes, preadipocytes, fibroblasts and vascular cells, in situ hybridization was performed to sections of epididymal fat pads from normal animals with sense and antisense *ob* riboprobes[6, 11]. When using the antisense probe, positive signals were detectable in all of the adipocytes in the section (Fig. 29-labeled Wt). Signals were not noted when the antisense probe was hybridized to sections of brain (data not shown). Hybridization of the antisense probe to sections of adipose tissue from C57Bl/Ks db/db mice was greatly increased, confirming the adipocyte specific expression of *ob* RNA and demonstrating a large increase in the level of *ob* RNA per adipocyte in these animals (Fig. 29-labeled db/db). Mice mutant at the *db* locus are massively obese as part of a syndrome that is phenotypically identical to that seen in C57Bl/6J *ob/ob* mice[12].

ob RNA was not synthesized by adipose tissue stromal cells separated from adipocytes. As expected, cells in the adipocyte fraction expressed *ob* RNA using Northern blots (Fig. 30). The same result was obtained using RT-PCR (data not shown). These data support the conclusion that only adipocytes express the *ob* gene. Data from cultured adipocytes confirm this conclusion. In these studies, 3T3-F442A cells were cultured using conditions that lead to lipid accumulation, as part of a cellular program leading to differentiation into adipocytes. *ob* RNA was not expressed in exponentially growing cells as well as in confluent 3T3-F442A preadipocyte cells which express early markers while differentiation of these cells into adipocytes led to the expression of detectable levels of *ob* RNA (Fig. 30)[13]. The level of *ob* RNA is extremely

REPORT

[illegible]

may be the result of resistance to the effects of the *ob* protein. If so, a secondary increase in the levels of *ob* RNA in adipose tissue would be predicted.

Hypothalamic lesions were induced in female CBA mice using the chemical Gold ThioGlucose (GTG)[19]. This treatment results in specific hypothalamic lesions, principally in the ventromedial hypothalamus (VMH), with the subsequent development of obesity within several weeks (manuscript in preparation). In our experience, a single intraperitoneal injection of GTG of .2 mg/gm body weight results in the development of obesity within four weeks. One month old female CBA/J mice (20-25 grams) were treated with GTG and the subsequent weight gain of treated and control animals is shown. (Table 2) Adipose tissue RNA was prepared from db/db mice and from those GTG treated animals that gained >20 gm. Northern blots showed a twenty-fold increase in the level of *ob* RNA in two month old db/db and GTG treated mice compared to normal animals (Fig. 3).

TABLE 2 Weight Gain in Gold ThioGlucose Treated Mice

| | <u>control (n = 41)</u> | <u>GTG (n = 93)</u> |
|-------------|-------------------------|---------------------|
| <10 g | 41, (100%) | 4, (4%) |
| 10 g - 20 g | 0, (0%) | 15, (16%) |
| >20 g | 0, (0%) | 74, (80%) |

Two month old female CBA/J mice were treated with goldthioglucose (GTG). Goldthioglucose (Sigma A0632) was administered intraperitoneally in normal saline solution at a dosage of 2.0 mg/g. Body weight of control and injected animals was recorded before and one month after the injection. Animals were housed five to a cage and were fed *ad libitum*. The amount of weight gained one month postinjection is shown in the table. Animals with a body weight gain greater than 20 g one month after injection were selected for further study.

In this report we show that the *ob* gene product is expressed exclusively by adipocytes in all adipose tissue depots. This result is consistent with the possibility that the protein product of the *ob* gene correlates with the bodies lipid stores. Moreover *ob* RNA is upregulated twenty fold in *db* mice and mice with hypothalamic lesions. In these animals, the actual increase in the level of *ob* RNA per cell is likely to be even higher than twenty fold since the adipocyte cell size is increased ~five fold in these animals (see Fig. 29) [14]. These data position the *db* gene and the hypothalamus downstream of *ob* in the pathway that controls body weight and is consistent with the hypothesis that the *ob* receptor is encoded at the *db* locus[18]. The molecular cloning of the *ob* receptor and/or the *db* gene will resolve this issue. The increase in the level of *ob* RNA in *db/db* and GTG treated mice also suggests a non cell-autonomous function of the *ob* gene product in fat cells[4, 5]. Thus, if the encoded protein acted directly on fat cells to inhibit growth or differentiation, the overexpression of the wild type *ob* gene in GTG treated mice would result in a lean phenotype.

The most parsimonious explanation of these data is that the *ob* protein functions as an endocrine signaling molecule that is secreted by adipocytes and acts, directly or indirectly, on the hypothalamus. Direct effects on the hypothalamus would require that mechanisms exist to allow passage of the *ob* gene product across the blood brain barrier. Mechanisms involving the circumventricular organ and/or specific transporters could permit brain access of a molecule the size of that encoded by the *ob* gene[20-22]. However, this

The fat cell signal(s) that are responsible for the quantitative variation in the expression level of the *ob* gene is not yet known but correlates with differences in adipocyte cell size. Adipocytes from db/db mice are five times as large as those from normal mice, with a cell size of ~1.0 μg lipid/cell[14]. Prior evidence has indicated that fat cell lipid content and/or size is an important parameter in determining body weight[23, 24]. It could be that each fat cell expresses a low level of *ob* RNA that further increases in proportion to the cell size. It is also possible that cell size is not the sensed parameter and merely correlates with the intracellular signal that increases the expression of the *ob* gene in adipocytes from db/db and VMH lesioned mice. In any case, the components of the signal transduction pathway regulating the synthesis of *ob* RNA are likely to be important in determining body weight. Genetic and environmental influences that reduce the level of expression of *ob* would act to increase body weight as would influences that decreased sensitivity to the encoded protein. The specific molecules that regulate the level of expression levels of the *ob* gene are as yet unknown, and await a determination of the level(s) of gene control that leads to quantitative variation in the level of *ob* RNA and an examination of the regulatory elements of the *ob* gene. The identification of the molecules that regulate the expression of the *ob* gene in adipocytes and those that mediate the effects of the encoded protein at its site(s) of action will greatly enhance our understanding of the physiologic mechanisms that regulate body weight..

OB RNA is expressed at high levels in human adipose tissue and at substantially lower levels in placenta and heart. The human OB gene maps to a large YAC contig derived from chromosome 7q31.3. In addition to confirming the relative location of the gene based on mouse-human comparative mapping, this study has identified 8 established microsatellite markers in close physical proximity to the human OB gene. Since mutations in mouse *ob* can result in a syndrome that closely resembles morbid obesity in humans, these genetic markers represent important tools for studying the possible role of the OB gene in inherited forms of human obesity.

ABBREVIATIONS

FISH: fluorescence in situ hybridization; GDB: Genome Data Base; kb: kilobase pairs; Mb: megabase pairs; PCR: polymerase chain reaction; STS: sequence-tagged site; YAC: yeast artificial chromosome.

MATERIAL AND METHODS

Northern blot analysis

Total RNA was prepared from adipose tissue using the method of Chirgwin et al. (1979). Northern blots, radiolabelling, and hybridizations were performed as described (Zhang et al. 1994). Northern blots of polyA⁺ RNA [human MTN, human MTN II, and human fetal MTN II] were purchased from CLONTECH (Palo Alto, CA), as were PCR primers used to generate the radiolabelled human actin probe.

STS development

STS-specific PCR assays were developed and optimized essentially as described (Green and Green, 1991a; Green et al. 1991b; Green, 1993; Green et al. 1994). Each STS is named using the prefix sWSS followed by a unique number. Details about the 19 STSs reported here are provided in Table 1, with additional information (e.g., PCR reaction conditions, complete DNA sequence) available in GenBank and/or the Genome Data Base (GDB). For the microsatellite-specific STSs, the oligonucleotide primers used in the PCR assays (Table 3) corresponded either to those employed for genotype analysis (Table 4) or those designed [most often with the computer program OSP (Hillier and Green, 1991)] using the DNA sequence available in GenBank.

Table 3. STSs in the YAC contig containing the human OB gene

The 19 chromosome 7-specific STSs mapped to the YAC contig containing the human OB gene (Figure 3) are listed. In each case, the designated sWSS name, relevant alias, GDB-assigned locus name, STS source, PCR primer sequences, STS size, and GDB identification number are indicated. The sources of STSs are as follows: YAC End [isolated insert end of a YAC (Green, 1993)], Lambda Clone [random chromosome 7-specific lambda clone (Green et al. 1991b; Green, 1993)], Genetic Marker [microsatellite marker (Green et al. 1994), see Table 2], YAC Insert [random segment from YAC insert], and Gene [gene-specific STS]. Note that for some genetic marker-specific STSs, the PCR primers used for identifying YACs (listed in this table) are different from those used for performing genotype analysis (Table 4), since the detection of YACs containing a genetic marker does not require amplification of the polymorphic tract itself. All of the indicated PCR assays utilized an annealing temperature of 55°C, except for sWSS494, sWSS883, sWSS1529, and sWSS2619 (which used 50°C), sWSS999 and sWSS1174 (which used 60°C), and sWSS808 (which used 65°C). Additional details regarding the STS-specific PCR assays are available in GDB.

The human OB-specific STS (sWSS2619) was designed using DNA sequence obtained from the 3' untranslated region of the cDNA. The human PAX4-specific STS (sWSS808) was developed using the following strategy. Oligonucleotide primers specific for the mouse Pax4 gene [GGCTGTGTGAGCAAGATCCTAGGA and GGGAGCCTTGTCCTGGGTACAAAG (Walther et al. 1991)] were used to amplify a 204-bp fragment from human genomic DNA (which was the same size product as that generated from mouse genomic DNA). This PCR assay was not suitable for identifying corresponding YACs, since a similarly-sized (200-bp) product was also amplified from yeast DNA. However, DNA sequence analysis of the PCR product generated from human DNA revealed substitutions at 20 positions among the 156 bases analyzed (data not shown). Using this human-specific sequence, a new primer (TTGCCAGGCAAAGAGGGCTGGAC) was designed and used with the first of the above mouse Pax4-specific primers (see Table 3). The resulting human PAX4-specific PCR assay did not amplify a significant product from yeast DNA and was thus used for identifying corresponding YACs.

Identification of YACs by PCR-based screening

Most of the YACs depicted in Figure 3 were derived from a collection of clones highly enriched for human chromosome 7 DNA [the chromosome 7 YAC resource (Green et al. 1995a)] using a PCR-based screening strategy (Green et al. 1995a; Green and Olson, 1990). In a few cases, clones were isolated by PCR-based screening (Green and Olson, 1990) of available total human genomic YAC libraries constructed at CEPH (Dausset et al. 1992; Albertsen et al. 1990) or ICI (Anand et al. 1990; Anand et al. 1989). Each YAC is named using the prefix yWSS followed by a unique number.

RESULTS AND DISCUSSION

Examination of the tissue expression of the human OB gene by northern blot analysis revealed that OB RNA is expressed at a high level in human adipose tissue and much lower levels in placenta and heart (Figure 3). The size of the RNA (~4.5 kb) was equivalent in human and mouse as well as in each of the expressing tissues. In these studies, five-fold higher signals were seen in 10 µg of total adipose tissue RNA as in 2 µg of polyA⁺ placental RNA. A five-fold lower signal was seen in polyA⁺ RNA from heart compared to placenta. It is estimated that the level of OB RNA is ~250-fold lower in placenta than in adipose tissue. In this experiment, OB RNA was not detected in any of the other tissues analyzed, including brain, lung, liver, skeletal muscle, kidney,

and pancreas. Additional experiments did not reveal OB RNA in spleen, thymus, prostate, testis, ovary, small intestine, colon, peripheral blood leukocytes, or in fetal brain, liver, or kidneys (data not shown). It is possible that OB is expressed at an undetectable level (by northern blot analysis) in these latter tissues or in other tissues that were not studied. The observed pattern of expression in human differs somewhat from mouse, in which ob RNA is detected almost exclusively in adipose tissue.

Comparative mapping of the ob gene region in the mouse and human genomes

The mouse ob gene is located on proximal chromosome 6 in a region homologous with a portion of human chromosome 7q. Genes within this segment include (from proximal to distal): Met protooncogene, the cystic fibrosis transmembrane conductance regulator (Cfr), paired box-containing gene 4 (Pax4), ob, and carboxypeptidase A (Cpa) (Zhang et al. 1994; Friedman et al. 1991). In mouse, genetic mapping was used to demonstrate that Pax4 is tightly linked to ob (Walther et al. 1991; Zhang et al. 1994). The physical distance between ob and Pax4 was found to be ~1 megabase pairs (Mb) (Zhang et al. 1994). Based on these comparative mapping studies, it was expected that the human OB gene would reside between PAX4 and CPA on chromosome 7q. Furthermore, since human CFTR (Heng et al. 1993) and PAX4 (Tamura et al. 1994) were mapped by fluorescence in situ hybridization (FISH) to 7q31.3 and 7q32, respectively, the most likely cytogenetic position of the human OB gene would be in the vicinity of the 7q31.3-q32 boundary.

Mapping the OB gene on human chromosome 7

An STS (sWSS2619) amplifying a small segment of the 3 untranslated region of the human OB gene was used to screen a collection of YAC clones that is highly enriched for human chromosome 7 DNA (Green et al. 1995a), and 9 YACs were identified (yWSS691, yWSS1332, yWSS1998, yWSS2087, yWSS3319, yWSS3512, yWSS4875, yWSS4970, and yWSS5004). To verify that these YACs contain the authentic human OB gene, 2 additional experiments were performed. First, each of the YACs was tested with a second human OB-specific PCR assay, and all were found to be positive (data not shown). Second, yeast DNA from each clone was digested with EcoRI and analyzed by gel-transfer hybridization using a human OB cDNA-derived probe. In all instances, a single hybridizing band was seen, and this band was the same size in the YACs and a P1 clone known to contain the human OB gene (data not shown).

Using the computer program SEGMAP (Green and Green, 1991a; C.L. Magness and P. Green, unpublished data) and other YAC-based STS-content data that we have generated for chromosome 7 (Green et al. 1991b; Green et al. 1994; Green et al. 1995a), the human OB gene

As depicted in Figure 3, the predicted orientation of the human OB-containing YAC contig is such that sWSS1734 is the centromeric-most STS (i.e., closest to CFTR) while sWSS2367 is the telomeric-most STS (i.e., closest to CPA). This orientation is predominantly based on comparative mapping data, which places Pax4 proximal and ob distal within the syntenic block present in mouse and human DNA (Zhang et al. 1994). The OB gene maps near the telomeric end of the contig, based on the placement of the OB-specific STS (sWSS2619).

While the contig shown in Figure 34 was deduced by SEGMAP without consideration of YAC sizes (thereby displaying STSs equidistant from one another), a similar analysis of the data by SEGMAP that accounted for YAC sizes indicated that the total size of the region covered by the contig is just over 2 Mb (data not shown). Thus, while all 8 of the microsatellite-specific STSs (Table 4) are contained within a genomic interval spanning roughly 2 Mb, the 3 closest to the telomeric end of the contig (sWSS1392, sWSS1148, and sWSS2367) are particularly close to the OB gene itself (perhaps within an interval as small as ~500 kb). In fact, all 3 of the latter STSs are present in at least 1 of the human OB-containing YACs. Of note, the interval between human PAX4 (sWSS808) and OB (sWSS2619) is estimated to be ~400 kb, whereas this region was predicted to span ~1 Mb in mouse (Zhang et al. 1994). Finally, 3 of the YACs within the contig (yWSS691, yWSS999, and yWSS2935) have also been analyzed by FISH, and each was found to hybridize exclusively to 7q31.3 (T. Featherstone and E.D. Green, unpublished data). One of these YACs (yWSS691) contains the OB-specific STS, while the other 2 clones contain the PAX4-specific STS. The latter results are generally consistent with the previous cytogenetic assignment of human PAX4 to 7q32 (Tamura et al. 1994). Based on these data, the human OB gene can be assigned to cytogenetic band 7q31.3.

EXAMPLE: Human Ob Peptide is Biologically Active in Mice

Groups of 10 ob/ob mice were treated by i.p. injection with 10 $\mu\text{g/g/day}$ recombinant (bacterial) human and murine ob peptide or saline. After four days, the group receiving saline gained 0.3 g. The group receiving murine ob lost 3.2 g. The group receiving human ob lost 2 g ($p < .01$ compared to saline controls). These groups were also tested for food intake. The data are shown in Table 5.

Table 5. Food intake/day (g) of treated ob/ob mice

| Treatment | Day 0 | Day 1 | Day 2 | Day 3 |
|-----------|-------|-------|-------|-------|
| saline | 13 | 13 | 12.9 | 13.2 |
| murine ob | 14 | 3 | 4 | 4.6 |
| human ob | 14.2 | 10.2 | 8.7 | 7.7 |

These data demonstrate that human ob is biologically active in mice.

EXAMPLE: A High Dose of Ob Affects Wild-type Mice

Wild type mice (C57Bl6J +/?) were treated with 10 $\mu\text{g/g/day}$ i.p. of recombinant murine ob, and body mass measured every four days. The results are shown in Table 6.

Table 6. Body mass of normal mice receiving ob

| Treatment | Day 0 | Day 4 | Day 8 | Day 12 | Day 16 |
|-----------|-------|-------|--------|--------|--------|
| saline | 22 g | 22 g | 22.5 g | 23 g | 22.5 g |
| murine ob | 22 | 20.5 | 20.7 | 20.8 | 21.8 |

These data demonstrate that ob affects the body mass of wild-type as well as obese (ob/ob) mice, albeit to a much smaller degree.

This invention may be embodied in other forms or carried out in other ways without departing from the spirit or essential characteristics thereof. The present disclosure is therefore to be considered as in all respects illustrative and not restrictive, the scope of the invention being indicated by the appended Claims, and
5 all changes which come within the meaning and range of equivalency are intended to be embraced therein.
